THE LANCET

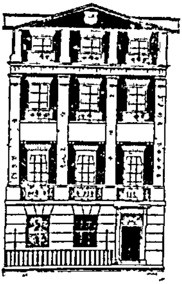
A JOURNAL OF BRITISH AND FOREIGN MEDICINE, SURGERY, OBSTETRICS,
PHYSIOLOGY, CHEMISTRY, PHARMACOLOGY, PUBLIC HEALTH, AND NEWS

FOUNDED BY THOMAS WAKLEY IN 182

VOLUME ONE

JANUARY-JUNE
1938
VOL No CCXXXIV

EDITED BY
EGBERT MORLAND, M.D., F.R.C.S
WITH THE ASSISTANCE OF
T. F. FOX, M.D., AND M. H. KETTLE, M.R.C.S.



PUBLISHED BY
THE LANCET LIMITED
7 ADAM STREET, ADELPHI, LONDON, W C 2

INDEX TO VOLUME I., 1938

REFERENCES AND ABBREVIATIONS

ders in search of a given subject will find it useful to bear in mind that the references are in several cases distributed under two or more separate but nearly synonymous headings. Institutions and Corporations with the right to the prefix Royal will be found under that prefix, with the exception of Hospitals, which will be found under that heading; and Medical Societies, which are separately indexed under Societies. All Universities are indexed under the word University. (A) = Annotation, (C) = Correspondence, (LA) = Leading Article, (ML) = Medico-legal, (NI) = New Inventions, (O) = Obituary, (PI) = Parliamentary Intelligence, (R) = Review, and (PCP) = Panel and Contract Practice.

A Concordance of page numbers and dates of issue will be found on page xxvi

AND ALLIED CONDITIONS

BY DANIEL T. DAVIES, M.D. Wales, F.R.C.P. Lond.
H. E. MANSELL, B.M. Oxon., F.R.C.P. Lond.
AND
LAURENCE O'SHAUGHNESSY, F.R.C.S. Eng.
With the coöperation of
VISCOUNT DAWSON OF PENN, P.C., M.D., B.Sc., F.R.C.P. Lond.

(From the Cardiovascular Clinic, Lambeth Hospital, London County Council)

THE experimental basis and technique of cardio-omentopexy was described a year ago in a special lecture at the Royal College of Surgeons of England which was introduced by Lord Dawson of Penn, honorary consultant to the Lambeth Cardiovascular Clinic, and published in this journal. The present paper contains an account of the further experiences of the clinic with cardio-omentopexy and other surgical means of supplementing a deficient coronary circulation.

In the Registrar-General's report for 1935 12,317 deaths are recorded from angina pectoris and coronary disease, and it seems probable that cardiac ischæmia played an important part in at least some of the enormous total of 70,504 deaths from myocardial disease. The total figure for carcinoma is 66,000.

The relation of coronary disease to sudden death has long been realised. Leyden, writing in the eighties, recognised the clear relation between degenerative changes in the myocardium and sclerosis of the coronary tree. Huchard agreed with Leyden, but by 1915 Sir Clifford Allbutt, while not denying the occasional existence of gross coronary obstruction as a cause of death, regarded angina as a symptom not of cardiac ischæmia but of some undefined type of nervous degeneration in the aortic plexus. To-day by common consent opinion has returned to the older view. On the clinical side Levine, in his clear and concise monograph, has grouped under the general heading of Angina Pectoris all the organic causes of cardiac ischæmia—coronary thrombosis, coronary sclerosis, and syphilitic aortitis—and he is emphatic that in fatal angina structural change is always present both in the myocardium and in the coronary tree. It is gradually being recognised that "chronic myocarditis" is a comparatively rare disease apart from cases of syphilitic or rheumatic origin, and that the greater proportion of cases so labelled, if carefully examined post mortem, show evidence of coronary disease.

Büchner, Weber, and Haager (1935) have published a careful record of 43 fatal cases of cardiac ischæmia in which the clinical findings are correlated with the post-mortem appearances both macroscopic and microscopic. They describe coronary thrombosis in an otherwise normal coronary tree, thrombosis complicating atheroma of the coronary arteries, hypertensive heart failure with gross atheroma of the tree but no gross obstruction, and syphilitic aortitis in which only the orifices of the vessels were affected. In every case the electrocardiograms were characteristic of cardiac ischæmia, and at autopsy careful examination of the heart revealed pathological changes in the myocardium. After obstruction of a main vessel, gross evidence of an old or recent infarct was invariably present; and where no actual block of the circuit was found but merely a general impairment of its lumen, scattered areas of recent necrosis or old fibrosis could always be detected in serial sections.

Under some conditions coronary occlusion is a fatal event, but the organism is often in a position to effect a remarkable degree of compensation; even successive attacks of coronary thrombosis may be survived and an astonishing degree of normal activity may be regained in the interval, sometimes years in extent, between the initial and the second attack. The mechanisms by which this natural compensation may be brought about have already been considered in previous papers. Although it is quite possible that there may be some subtle mechanism of which we know nothing, there are only two methods for the existence of which we have experimental and clinical evidence. One of these is anastomosis between the right and left coronary arteries, and the other is the process by which the heart may supplement its blood-supply from the parietes. The first mechanism is clearly of no avail when a diffuse sclerosis affects the entire coronary tree, and the second is only available if partial or complete destruction of the epicardium takes place so that adhesions may form between the heart and the parietal pericardium. After a coronary thrombosis only a small proportion of patients form adhesions between their infarct and the parietal pericardium, but this mode of compensation is important because it alone can be initiated or supplemented by surgery.

In a previous paper examples of the beneficial association of pericarditis with coronary disease were reviewed—Sternberg's classical case of "pericarditis epistenocardica," the histories cited by Monckeberg, and also Sir Clifford Allbutt's doctor patient who returned to active practice after a severe attack of angina complicated by pericarditis. Chance has provided us with an excellent example of natural compensation in angina pectoris.

The father of one of our operated patients is now aged 68. For several years he suffered from angina for which he received the usual medical treatment. Three years ago he was suddenly seized by a more violent attack of pain in his chest than he had previously experienced, and in a state of collapse he was removed to hospital, where he passed some days in a critical state and grave doubts of his ultimate recovery were expressed. However, he recovered and after some weeks in bed returned home. He gradually resumed general activity and was amazed to find that his angina had disappeared. He remains free from pain and our interpretation of his recovery is that he suffered an attack of coronary thrombosis and adhesions formed with the parietes.

Moritz demonstrated by injection studies the vascularity of pericardial adhesions, and similar results have been obtained by one of us (H. E. M.) in the pathological department at Lambeth. In cases of pericarditis following coronary thrombosis it was possible to demonstrate vascular continuity between the coronary tree and the vessels of the parietal pericardium, the inferior sternopericardial ligament, and the diaphragm. It may be mentioned that the vascularity of the structures surrounding the heart in human beings appears to be much greater than in experimental animals.

A review of the literature of coronary disease shows that methods of initiating or supplementing the collateral blood-supply to the heart are engaging the attention of physicians both in America and in Germany. Hochrein in his latest monograph (1937) states that "we have learnt to recognise that pericarditis is not a complication of coronary thrombosis but a natural attempt at healing—its presence is to be welcomed rather than deplored," and he goes on to discuss the theoretical possibility of encouraging the formation of pericardial adhesions when nature has failed to provide them. This theoretical possibility has been carried into practice in some of our cases with apparently beneficial results.

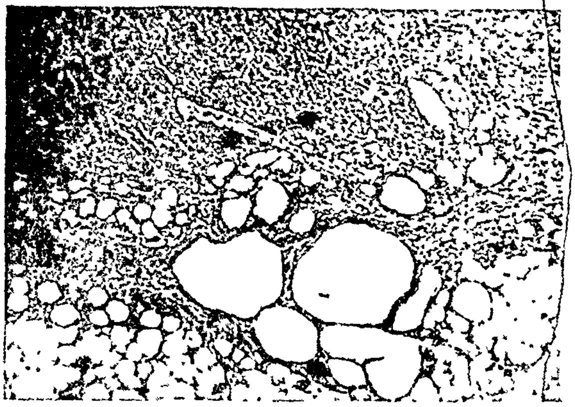

FIG. 1.—Section through junction between myocardium (above) and omentum (below) a week after operation. A primitive vessel is growing from the omentum into the heart muscle. (× 60.)

Experimental Basis of Cardio-omentopexy and Allied Operations

Experimental work on various methods of augmenting the blood-supply to the heart has been in progress at the Buckston Browne farm of the Royal College of Surgeons of England since April, 1933. The results previously obtained have been recorded in various publications, and a further paper containing details of modifications in technique is in preparation.

In animal experiments we have shown that an omental graft attached to the heart is compatible with the highest degree of physical exertion. One of our greyhounds completed a full course (525 yards) without distress after his recovery from two operations—at the first the descending branch of the left coronary artery was tied and at the second the graft was applied.

We have also shown that vascular connexions rapidly form between the graft and the myocardium, whether it is attached to normal muscle, to the site of a recent infarct, or to the site of an old fibrous infarct; this is important because these are the three conditions with which one might be confronted at operation. New vessels may be observed microscopically at the end of a week (Fig. 1), and at the end of three weeks complete injection of the coronary tree may be carried out from the graft with a suspension of indian ink. As time passes the vascular connexion increases and these injections may be made with barium paste (Fig. 2). The oldest specimen examined—that of a greyhound killed eighteen months after operation—showed that there was a marked increase in the normal mediastinal vessels and that these too had made connexions with the graft and with the myocardium. It is a fundamental point that cardio-omentopexy brings a new blood-supply to the heart from the abdominal aorta and also supplements the normal collaterals in the mediastinum and gives them access to the ischæmic heart. It is also important to realise that the graft forms direct connexions with the myocardium at its point of attachment and that its vessels anastomose with branches of the coronary tree, and therefore blood brought by the graft may be distributed to all parts of the heart. In other words, exact placing of the graft in relation to any localised area of ischæmia which it is desired to influence is not essential.

Lezius (1937) has shown that the lung can form extensive vascular adhesions with the heart when the fibrous pericardium is removed; he found that under these conditions he could ligature the descending branch of the left coronary artery without causing the usual infarct. In cardio-omentopexy the lung often adheres to the graft and probably assists in revascularisation, but we have so far only used cardio-pneumonopexy when the usual operation was impossible.

In the most recent of our laboratory experiments we have shown that the production of intrapericardial adhesions by the use of a special preparation—Aleuronat—provided us with an additional and simple means of revascularisation. In this way a route is afforded for revascularisation from the mediastinal vessels, but the method is inferior to cardio-omentopexy in that reinforcement of these vessels does not occur.

In our earlier experiments and operations the omental graft was always sutured to the heart; more recently we have been able to obtain equally firm attachment of the graft by suturing it to the pericardium only and applying aleuronat paste between the graft and the heart. We have also been able to demonstrate that the vascular continuity under these conditions is of the same order as when sutures are employed. This is technically important, for our experience has shown the danger of placing sutures in a friable and degenerate heart.

The Operations

Four types of operation were used in this series:

Cardio-omentopexy (Fig. 3) in which a left transpleural exposure of the heart is used, the pericardium is opened and a pedicled graft of the great omentum is brought through the diaphragm and attached to the heart.

Transpleural pericardiotomy in which the pericardium is opened after a left transpleural exposure, aleuronat paste is inserted and the pericardium is closed.

Extrapleural pericardiotomy in which the seventh costal cartilage and part of the xiphoid process are resected in Larrey's angle, the pericardium is opened and the sac treated with aleuronat.

Cardio-pneumonopexy (Lezius) in which after a left transpleural approach the pericardium is opened and a portion of lung is attached to the heart.

The Cases

The series consists of twenty cases. Patients were selected for operation who showed unequivocal evidence of cardiac ischæmia and who had failed to benefit by medical treatment. The majority were suffering from angina of effort. The aim of the operation in every case was to supplement the coronary circulation from without. The actual technique was modified to suit the individual patient and varied from complete cardio-omentopexy to simple pericardiotomy for insertion of the irritant aleuronat to encourage pericardial adhesions.

The cases will be considered in two groups—the first and larger group consisting of patients suffering from angina pectoris, the second and smaller group consisting of patients with other symptoms of cardiac ischæmia.

GROUP I: ANGINA PECTORIS

Of the fifteen members of this group (Table I) some were bedridden, others were in hospital, and the rest with one exception suffered from angina of effort of such degree as to curtail their ordinary activity. The exception is Case 13, in which the pain was not severe and was due to his previous coronary thrombosis, but in view of his age we considered operation justifiable.

CASE 1

A cosmopolitan of varying occupations, aged 65, was transferred to Lambeth Hospital on July 28th, 1936, from St. Stephen's Hospital (L.C.C.), where he had been admitted on July 7th after an attack of severe angina on the previous day. The pain had been most severe, lasting for four hours without relief from amyl nitrite and accompanied by much dyspnœa. He had had eight attacks during the previous four years, and from the first attack had limited his activities as far as possible He was not normally breathless on exertion. He had had severe insomnia for the past six or eight months. He was a heavy smoker until three years ago He gave a history of malaria and three laparotomies—for appendicitis, adhesions, and gastro-enterostomy. A paternal uncle had "dropped dead of angina."

Physical *examination* showed a grey-haired, well-nourished man with somewhat protruding eyes His tongue was clean. There was no enlargement of the thyroid but slight tremor of the fingers. The radial artery was slightly tortuous but not thickened. The heart was not enlarged, the sounds were normal, and there was a soft apical systolic murmur. The blood pressure was 116 mm. systolic and 72 diastolic. The lungs were emphysematous. The abdomen showed three well-healed scars. The right pupil was larger than the left and the knee-jerks and ankle-jerks were not elicited. The urine was normal and the blood urea 32 mg. per 100 c.cm. The Wassermann reaction was negative. X ray examination showed a large heart shadow. The basal metabolic rate was −40 per cent. The electrocardiogram showed the S-T interval raised and convex downwards in leads II and III.

Cardio-omentopexy was performed on August 17th The heart was found to be free of pericardial adhesions. There was no difficulty in obtaining omentum in spite of three previous laparotomies. At the end of operation the upper left intercostal nerves were injected with 1 per cent. novocain. The pulse-rate was 96. Except for an immediate mild bronchitis recovery was uneventful. He was allowed up four weeks later and took his own discharge on Dec. 10th, the blood pressure being 160 mm. systolic and 90 diastolic. There were no further attacks of angina. Movement of the left diaphragm was seen for the first time 3¼ months after operation. Serial electrocardiograms showed a gradual emergence of a Q wave in lead III.

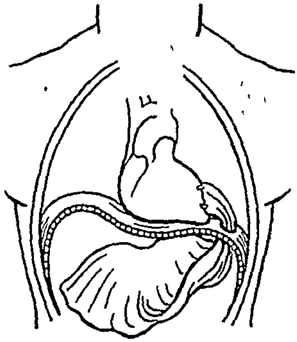

FIG. 3.—Diagram illustrating cardio-omentopexy in man

Since leaving hospital he has been able to lead a life of normal activity without symptoms.

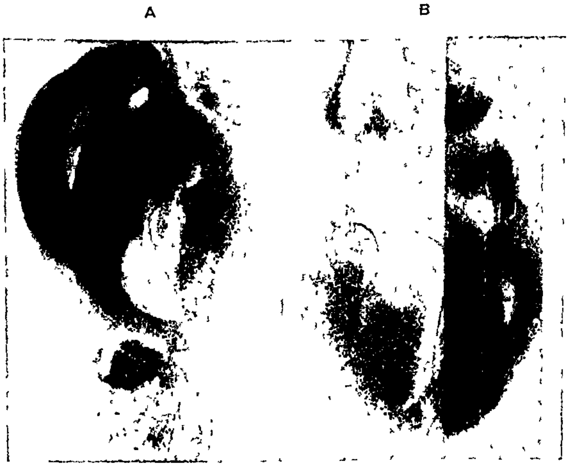

FIG. 2a.—Greyhound's heart injected with barium paste through the graft, eighteen months after cardio-omentopexy. Left side with graft attached.

FIG 2b.—Right side of the same heart.

CASE 2

A male, aged 71, who had retired from the Burma Police thirty years previously, was admitted to Lambeth Hospital from Dr. Dean Pollard of Bedford on July 31st, 1936, complaining of attacks of pain, beginning at the base of the neck and spreading over the heart and down the left arm. The first attack had occurred suddenly during exertion three years previously. They had become increasingly frequent—now almost daily—but not more severe. The pain was always related to exertion, emotion or, during sleep, to nightmare, and was relieved by nitroglycerin He was not breathless on exertion between the attacks. He gave a history of appendicectomy in 1912.

Physical *examination* showed a well-nourished man of rather plethoric facies. His remaining teeth were septic. The radial arteries were tortuous and thickened. The size of the heart was masked by emphysema. The sounds were very distant but not spaced, and there was a soft systolic murmur at the apex. The blood pressure was 205 mm. systolic and 105 diastolic. Nothing abnormal was found in the lungs, abdomen, and central nervous system. The urine was normal and the blood urea 44 mg. per 100 c cm. The Wassermann

TABLE I.—CASES OF ANGINA PECTORIS

Case	Age.	Sex.	Diagnosis.	Operation.	Date.	Result.
1	65	M.	Angina of effort.	Cardio-omentopexy by suture only.	Aug. 17, 1936	Symptom-free.
2	72	M.	„ „		Sept. 25 „	Died of uræmia three months later.
4	65	F.	*Angina, hypertension, bundle-branch block.*	Cardio-omentopexy by suture with insertion of aleuronat.	Oct. 16 „	Symptom-free.
5	60	M.	Angina of effort.		Jan. 22, 1937	„ „
7	67	F.	„ „	..	Feb. 26 „	Died on table.
8	56	M.	„ „	Pericardiotomy for insertion of aleuronat.	Mar. 5 „	Symptom-free, at work.
9	50	M.	Coronary thrombosis, angina of effort.	Cardio-omentopexy with aleuronat only.	Mar. 12 „	„ „
10	41	M.	Angina of effort.		April 16 „	Much improved, at work.
11	56	M.	„ „		April 23 „	Improved, at work.
13	43	M.	Coronary thrombosis.		May 7 „	Symptom-free, at work.
14	56	M.	Angina of effort, auricular fibrillation.	Transpleural pericardiotomy for insertion of aleuronat.	May 28 „	Died two months later.
15	65	F.	Coronary thrombosis, angina of effort.	Cardio-omentopexy by suture only.	June 4 „	Much improved, discharged to convalescent home.
17	65	M.	Angina of effort.	Cardio-omentopexy with aleuronat only.	July 2 „	Died two months later.
18	62	F.	„ „		July 2 „	„ „
19	55	M.	„ „	Pericardiotomy for insertion of aleuronat.	Aug. 25 „	Discharged from hospital, in statu quo.

reaction was negative. X ray examination showed that the heart was not enlarged. The electrocardiogram showed left axis-deviation, with inversion of the T waves in lead I. The S–T interval was depressed in lead I and raised in lead III.

While *in hospital* he had two attacks of angina: a mild attack in our presence while walking too fast, and a severe attack lasting six or seven minutes while straining at stool. On August 17th he developed acute tonsillitis and was sent home to recuperate on the 26th. He was readmitted on Sept. 23rd; he had a severe attack lasting twenty minutes on the station, after climbing a flight of 24 steps twice, and had to take two tablets of nitroglycerin before being able to proceed. On examination he looked fit and the throat was clear. The blood pressure was 208 mm. systolic and 118 diastolic. There were no basal râles and the urine was normal. The electrocardiogram showed no change.

Cardio-omentopexy was performed on Sept. 25th. The pericardium was tense, and the heart enlarged but free of adhesions. The pulse-rate at the end of operation was 72, and the blood pressure two hours later was 154 mm. systolic and 92 diastolic. The electrocardiogram showed no change.

He developed purulent bronchitis which lasted a week. On Oct. 4th he had two attacks of angina following visiting hours, the second needing an injection of morphia. There was a slight attack two days later. On Oct. 12th he had a severe attack (after being allowed up for two hours by mistake), only partially relieved by nitroglycerin and morphia and leaving numbness of the left arm. He subsequently became subject to frequent attacks of pain, occurring day and night and not related to exertion. The pain was relieved by nitroglycerin but not by an injection of sterile water. Attacks did not occur when his attention was occupied. He began to get up at the end of four weeks and was discharged home on Nov. 1st, showing no ill effects from a long car journey. His wife wrote on Nov. 30th: "He is immensely improved both mentally and physically, and I think that he improves slowly all the time. If it were not for the occasional pains, he would be in perfect health." During the following week there was a return of severe pain and insomnia. The pain soon eased off, only to be followed by breathlessness which became more and more distressing until Dec. 19th, when he was *readmitted* to Lambeth Hospital.

On examination he looked haggard and desperately ill. There was Cheyne-Stokes breathing, but in spite of the violence of the hyperpnœic phase he had no angina. The pulse was of fair volume and rate 100. The heart sounds were of very poor quality and there was gallop rhythm. The blood pressure was 140 mm. systolic and 100 diastolic. Râles were audible at the left base. There was no œdema but the urine was loaded with albumin. The tongue was dry and coated. The electrocardiogram showed much increase in voltage of the S waves in lead III and changes in the S–T interval in leads I and III. A diagnosis of uræmia was made. The blood-urea proved to be 116 mg. per 100 c.cm. and the blood calcium 10·4 mg. He improved

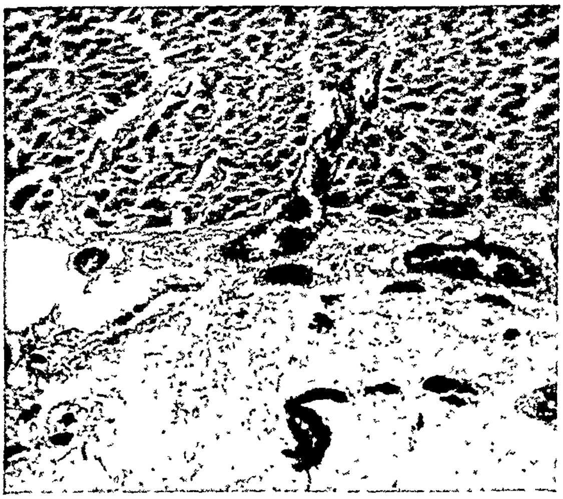

FIG. 4.—Section from Case 2 through junction between myocardium and omentum three months after operation. A vessel is seen entering the myocardium.

for a few days with treatment but changed suddenly for the worse on Dec. 27th and died that night

Post mortem examination showed the operation wound to be firmly healed and there had been complete restitution of the thoracic cage The graft was firmly attached to the heart, which was removed for injection The right pleural cavity contained free fluid in excess but the lung was normal The lower lobe of the left lung was collapsed The abdomen contained an excess of free fluid but the viscera, including the colon were normal and the graft could be seen in place passing through the diaphragm *The kidneys showed chronic interstitial nephritis* and there was advanced atheroma of the abdominal aorta Injection of the graft with a watery suspension of indian ink was carried out from the abdominal aorta after removal from the body A pressure of 100 mm of mercury was used and the technique was identical with that employed in the experimental series A very profuse injection of the parietal pericardium was obtained and the ink eventually reached the chambers of the heart The specimen was fixed in formalin and on section it was possible to see ink lying in the myocardium Stained sections showed new vessels running from the omentum into the myocardium (Fig 4) There was *diffuse sclerosis of the* coronary tree, the lumen being obliterated at one point on the left descending branch but there was no actual infarction of the myocardium

CASE 4

A missionary s widow, aged 65, was admitted to Lambeth Hospital from Dr Lyne of Hove on Oct 1st, 1936 with a history of angina of twelve years duration It had formerly been relieved by amyl nitrite but now needed Omnopon Attacks were often occurring at night or in the early morning if she had become overtired the evening before She had been practically confined to bed for eighteen months past and was unable now to wash herself She was also liable to attacks of rapid and irregular pulse, lasting about half an hour and causing considerable distress at the time She also complained of headache and a bursting feeling in the head She had led an exceptionally adventurous and strenuous life often at high altitudes She had had pleurisy several times and pneumonia eight years ago There is a family history of pulmonary tuberculosis A sister died of a stroke and another has angina

On *examination* she was obese The teeth were well stopped the throat clear The apex beat was in the 5th intercostal space in the anterior axillary line The mitral first sound was very low and the aortic second sound accentuated and ringing There was a very soft to and fro murmur at the apex and in the aortic area The blood pressure was 247 mm systolic and 117 diastolic Nothing abnormal was found in the chest and abdomen The knee jerks and ankle jerks were not obtained There was no œdema and the urine was normal The Wassermann reaction was negative X ray examination showed a large heart The electrocardiogram showed a right (old terminology) bundle branch block, with very large amplitude of the Q R S complexes in leads I and III

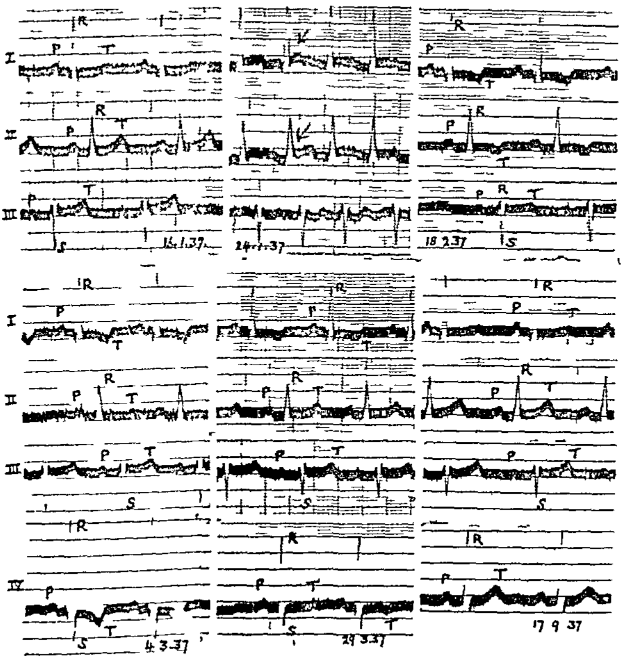

FIG 5 —Serial electrocardiograms taken in Case 5 Cardio omentopexy with insertion of aleuronat was performed on Jan 22nd

(The bundle block was known to have been present in 1930.) She was treated for fourteen days with a starch free diet, general massage, and sedative drugs

Cardio omentopexy was performed on Oct 16th The inferior sternopericardial ligament was fatty and well marked A large fatty graft was secured and sutured to the heart, which was free of adhesions, aleuronat in addition being inserted At the end of operation the pulse rate was 69 and the blood pressure 170 mm systolic and 90 diastolic Recovery was interrupted by a paroxysm of auricular fibrillation which began 30 hours afterwards *and ceased spontaneously 9½ hours later* It was *accompanied at the onset by severe angina* There was a *moderate* rise of evening temperature for four days Two anginal attacks occurred in the first fortnight and none subsequently *General massage was restarted after five weeks* and she was allowed to wash herself In six weeks the blood pressure had returned to 240 mm systolic and 112 *diastolic* On Christmas Day, ten weeks *after operation* she was up and about the ward for two hours without ill effects During January she had some further attacks of paroxysmal fibrillation accompanied by pain They ceased as soon as she was put on quinidine She was transferred to St Benedict s Hospital for convalescence on Feb 3rd, sixteen weeks after operation The blood pressure was 230 mm systolic and 116 diastolic, the electrocardiogram showed no change and there were still signs of collapse at the left base

She was discharged from St Benedict s Hospital on March 18th and has gradually regained her activity *There have been no more attacks of angina* There was a brief return of auricular fibrillation in June when she had been overdoing things, but it responded at once to quinidine Eight months after operation X ray examination infarction. There were many patent blood-vessels in the graft lying over the epicardium, and there was also very vascular subepicardial zone corresponding to it, as seen in Case 2. The specimen is receiving further histological study.

CASE 18

A housewife, aged 62, was admitted to Lambeth Hospital on April 23rd, 1937, with a six years' history of angina pectoris. During the last year her activity had been so much curtailed that she had been unable to go shopping. Pain had occasionally occurred in bed. She was also very short of breath, had a bad cough, and slept badly. She was in bed for three months with rheumatic fever at the age of 18. There was no family history of angina. She continued to have attacks of angina while in hospital, and after a severe attack on June 30th she was referred to the clinic.

Physical *examination* showed a rather obese and florid woman. There was gross oral sepsis. The heart was enlarged, the sounds were soft and spaced with a well-marked gallop rhythm, and there was a very soft mitral systolic murmur. The arteries were not thickened and the blood pressure was 186 mm. systolic and 106 diastolic. There were râles at both bases; the vital capacity was 1500 c.cm. and the chest expansion ¼ in. The abdomen was normal and the central nervous system also except for small irregular sluggish pupils. There was no œdema. The urine and kidney function tests were normal and the blood-urea 26 mg. per 100 c.cm. The Wassermann reaction was negative. X ray examination showed an enlarged heart. The electrocardiogram showed left axis-deviation and inversion of the T waves in lead I. The duration of Q R S was 0·12 sec.

All her teeth were extracted. When re examined lo fore operation, gallop rhythm was only just discernible, aft the heart sounds were still tic-tac. There were very end basal râles and the blood pressure was 164 mm. Recc lic and 90 diastolic. leucoc and w*dio-omentopexy* was performed on July 2nd. The further nerve was crushed and a good graft obtained. systolicg was emphysematous and a bulla could be seen increasirly. The pericardium was tense and contained He im fluid. The surface of the heart showed a pale during Jleuronat was applied and the graft sutured to the of attache pericardium. A well-marked inferior sterno- similar, eal ligament and the lung fell nicely into apposition. the pain e-rate at the end of operation was 110 and the spontaneessure 104 mm. systolic and 66 diastolic. examinatmmediate progress was good. She developed increase, bronchitis and a urinary infection, both of which in lead down. Tachycardia and leucocytosis however, notchied for no obvious cause, and three and a half weeks still uoperation she had an anginal attack lasting fifteen ites. Her condition then slowly improved and by gust 9th she had been up twice without ill effects. ne following day she had two further attacks, and was confined to bed again. Eight weeks after operation she was still confined to bed and was getting frequent attacks of pain, relieved by nitroglycerin. On examination the heart was not enlarged. There was tachycardia but no gallop rhythm. Very slight pitting œdema was present over the tibiæ. The blood pressure was 150 mm. systolic and 84 diastolic. She died suddenly on Sept. 6th, two months after operation.

At *post-mortem examination* the wound was found soundly healed. The left lung and the inferior sternopericardial ligament were adherent to the graft, which was itself adherent to the heart. There was complete adhesion of the pericardium, and on separation of part of it several bleeding points could be seen on the surface of the heart. The heart showed hypertrophy of the left ventricle, with diffuse fibrotic changes in the myocardium. The coronary tree showed diffuse sclerosis and atheroma, but detailed examination of its ramifications was not carried out as the specimen is being preserved for further histological study of the adhesions, which initial examination shows to be highly vascular. The lungs were normal. The abdominal viscera were not abnormal and the graft could be seen the diaphragm at its normal site. The

CASE 19

An engineer, aged 55, was admitted to Lambeth Hospital from Dr. Blair Macaulay of Liverpool on July 26th, 1937, complaining of breathlessness on exertion of gradual onset, 3½ years ago, when working long hours under bad conditions on the Mersey Tunnel. Soon afterwards he had begun to get attacks of pain across the chest on exertion. At the time of admission he could not walk more than twenty or thirty yards without inducing an attack. His previous history was negative except for a herniotomy ten years ago, and there was no family history of angina.

Physical *examination* showed a lean but well-nourished man of florid complexion. The tongue was moist and clean, but the gums round his six remaining teeth showed pyorrhœa. The heart was not enlarged, the sounds were only just audible, and there were no murmurs. The radial and brachial arteries were moderately thickened and the blood pressure was 100 mm. systolic and 70 diastolic. There were a few persistent râles at the right base and a constant cough was noticeable. The chest expansion was 1½ in. Nothing abnormal was found in the abdomen. The urine contained a trace of albumin. The blood-urea was 44 mg. per 100 c.cm. and the urea-concentration test was normal. The Wassermann reaction was negative. X ray examination showed a normal heart shadow. The electrocardiogram showed a low voltage, the Q R S complexes measuring 1 mm. in lead I. The T waves were upright in all leads but low in lead I.

He was treated with breathing exercises and a stimulating expectorant mixture, and his remaining teeth were extracted. His cough and sputum persisted, however, and it was decided that he was only fit for pericardiotomy via Larrey's angle. This operation was advised in the hope that he might improve sufficiently to allow cardio-omentopexy to be performed at a later date. His vital capacity before operation was 3150 c.cm.

Pericardiotomy via Larrey's angle was performed on August 28th. The heart was greyish-yellow in colour. In spite of the minor nature of the operation he developed purulent bronchitis with mild pyrexia but no leucocytosis. He was allowed up for the first time two and a half weeks after operation and was discharged home for personal reasons on Sept 23rd, his blood pressure being only 96 mm. systolic and 66 diastolic. He was able to walk round the grounds and up one flight of stairs without pain or breathlessness.

His improvement was short-lived and he now reports that his condition is as bad as before the operation.

To sum up, of these fifteen cases of angina submitted to operation we record five deaths: one of uræmia in a man aged 72, three months after operation; the second at operation through rupture of a friable ventricle; the third of pulmonary infarction two months afterwards; the fourth suddenly in the second month, following a stormy convalescence complicated by pneumonia, empyema, and necrosis of a costal cartilage; and the last suddenly for no apparent cause, again two months after operation. On the other hand, of the ten who lived we have knowledge that eight have eventually enjoyed freedom from angina, and of the eight men seven are back at work.

(*To be concluded*)

MENTAL AFTER-CARE ASSOCIATION.—The object of this association is to provide some form of assistance, including homes for convalescence, for the poor treated in public mental hospitals to bridge over the difficult period intervening between recovery and return to normal life. Later some are helped to find suitable employment. This year nearly 4000 people have been befriended by the association. It also assists authorities who are adopting the boarding-out system for chronic patients. An earnest appeal for funds to carry on and extend this work is being made. Contributions should be sent to Miss E. D. Vickers, 354, Grand Buildings, London, W.C.2.

Dr DELISLE GRAY said that young men in hospital did not know what general practice was Before specialising, they should learn what general practitioners did they should first spend 6–12 months in general practice

Dr BARBER made it clear that he had not suggested that the general practitioner should not examine the patient , but that without the case history the examination might be futile When the practitioner came into a home he should bring a therapeutic influence, but anxiety was likely to return after he left Here the bottle of medicine was valuable as an emblem of his continuing authority

Medical Treatment

Principles and Their Application Editor GEOFFREY EVANS F R C P , consulting physician, St Bartholomew's Hospital London Butterworth 1951 Pp 1398 £5 5s

AT a time when so many new drugs and methods are being introduced, it requires both skill and courage to produce a book on medical treatment—skill in selection and courage in rejection Dr Geoffrey Evans has exercised both virtues, and, marshalling a team of more than fifty contributors, has produced a volume likely to prove a standard work of reference for doctors throughout the world The series of monographs, covering the whole field of medical treatment, reflect the enormous advances that have been made during the past few years The information is up to date, including such topics as 'Aureomycin' and chloramphenicol, aminopterin, vitamin B_{12}, the rice diet, and the treatment of acute renal failure by intragastric drip , and though the articles naturally vary both in form and quality, all of them are practical Some, such as that by Professor Haddow on the chemotherapy of cancer are fully annotated reviews , others, such as an excellent section on diseases of the gall-bladder by Dr E R Cullinan, are based on personal practice and unsupported by references Dr Paul Wood presents a clear and reasoned account of the treatment of heart disease, and the chapter on pulmonary tuberculosis by Dr Robert Coope and Mr Price Thomas is worthy of its authors Sections on geriatrics, rehabilitation, and the treatment of dental sepsis are included , and dermatology, pædiatrics, the tropical diseases, and industrial hazards are expertly discussed

Since treatment is not stereotyped, it is inevitable that certain statements invite criticism It seems a pity, nowadays, still to recommend an acid ash diet in the prevention of renal calculi, to surround adiposity with an aura of mystery, and even to refer to the use of autogenous vaccines in the treatment of intestinal toxæmia. Many physicians would not agree that the mercurial diuretics are reliable in the treatment of the œdema of type II nephritis, and the usual dosage of penicillin in subacute bacterial endocarditis is now higher than that recommended These are, however, minor points , and we welcome a book that deserves, and is sure to receive, an enthusiastic reception

Congenital Heart Disease

(2nd ed) J W BROWN, M D Lond , F R C P , physician to the Grimsby General Hospital London Staples Press 1950 Pp 344 30s

SINCE the first edition of this book appeared ten years ago the advances in diagnosis and treatment of congenital heart-disease have been so remarkable that Dr Brown has seen fit to rewrite most of it , his bibliography of over 700 references bears witness to the work this has entailed For the most part he considers cyanosis a useful guide in classification, and thus follows Abbott , but he points to the tendency in congenital heart lesions towards anatomical adjustment and adaptation In a useful chapter on differential diagnosis he emphasises the value of the early history, such as routine school-entrance records provide, and a proper appreciation of physical signs His wide experience of school-children adds weight to the statement that current views on prognosis of the cyanotic group require revision , puberty is not always an adverse factor in such cases, yet the significance of a rising blood-count is serious He advocates regular periodical observation of children with congenital heart disease so that cardiac enlargement can be assessed, but he decries an unnecessarily gloomy outlook Valuable advice is given on the general care of patients, on their education, and on their management when pregnant Though evidence is conflicting, he firmly believes that maternal rubella in the first three months of pregnancy is so important that therapeutic abortion in such cases is justified

The many cardiologists and practitioners who have eagerly awaited this second edition will not be disappointed by it

Chemotherapie der Tuberkulose mit den Thiosemikarbazonen

GERHARD DOMAGK and others Stuttgart Thieme 1950 Pp 405 D.M 60

THE object of this work is to review the experimental and clinical results obtained with the thiosemicarbazones in the treatment of tuberculosis Three chapters are by Domagk the first two on the bacteriology and pathology of tuberculosis, while well presented, include a number of unjustifiably dogmatic statements , the third gives the experimental results obtained with the drug The other chapters deal with clinical results in various forms of tuberculosis skin, upper respiratory, glandular, intestinal, genito urinary, osteo articular, and pulmonary (four chapters) Each author gives his own experience , there has been no combined study of dosage and duration of treatment The best chapters are by Kalkoff, on skin tuberculosis (a remarkable study), and by Malluche, on the local treatment of cavities In pulmonary tuberculosis the results are suggestive but by no means conclusive, and the work is far from reaching present standards required for the evaluation of chemotherapy On the other hand the production of the book—the paper, the print, and the quality of the illustrations—surpasses anything nowadays seen in this country

Essential Urology

FLETCHER H COLBY, M D , chief of the urological service, Massachusetts General Hospital Baltimore Williams & Wilkins London Baillière, Tindall, & Cox 1950 Pp 580 61s 6d

THIS sound book is intended for the senior student The teaching is essentially practical and good illustrations abound Few will disagree with the author's condemnation of the various ingenious but dangerous rigid stone-extractors for the cystoscopic manipulation of ureteric calculi, or with his candid admission that many cases of chronic prostatitis are resistant to all known forms of treatment We confidently recommend the work

The Alkaloids

Chemistry and Physiology Vol I Editors R H. F MANSKE , H. L HOLMES New York Academic Press 1950 Pp 525 $10

THIS is the first of a series of four volumes, to which it seems that a fifth, on the pharmacology of the alkaloids, may be added

Volume I is divided into seven sections each written by an expert The first two deal with what may be called the natural history of the alkaloids thus R H F Manske describes their botanical distribution, and gives lists of natural orders and botanical families of alkaloid yielding plants, with charts of these orders, based on Hutchinson's diagram suggesting probable lines of evolution in flowering plants Manske hints at the possibility of a classification of plants on the basis of their chemical components He also discusses, evidently from practical experience, the isolation of the mixture of alkaloids usually present in a plant, and the separation and purification of its components W O James surveys critically the results of many workers bearing on the problems of where, how, and why biogenesis of alkaloids occurs in plants The remaining sections are chemical all five are written by chemists, primarily for chemists, and as the case history When the student as a clerk took a patient's history at the bed side, the answers he got were really the patient's impression of the answers, in general practice the doctor knew these answers from his own observation Living in the neighbourhood, the practitioner gained a knowledge of his patient by observing his heredity as well as his environment—which was very important knowledge when the stress syndrome began to develop One often observed in different members of a family a tendency to break down in the same way

There were two conflicting views of the scope of general practice One was that as medicine and surgery and the allied specialties became more and more complicated, the general practitioner must become an intelligent signpost to the outpatient departments Dr Barber believed the opposite to be true He believed that it was the general practitioner's duty to oversee the specialist investigations, and when he passed on a patient to a specialist or a hospital department, it was part of his duty to see that the specialty was applied properly and according to the patient's needs The practitioner should not think "Oh, I've sent him to hospital Now I can forget about him until he comes back" Whether a patient was well or ill, he should have a general practitioner who felt responsible for him Such over all responsibility sometimes took the general practitioner a good deal away from academic medicine, but this responsibility for the patient in sickness and in health was the driving force of general practice The emergency call might be for something trivial But general practice consisted not so much in treating the triviality which caused the panic in the home and perhaps the neighbourhood, as in treating this "herd panic" This was especially true of births and deaths At the birth of a first baby not only the mother but the expectant father and the grandparents needed treatment, and the handling of them should be as effective as that of the confinement Death, too, did not affect only the person who was going to die The practitioner could make all the difference between a never forgotten blow and an event that drew together the remaining members of the family

It could be argued that general practice was degenerating into the treatment of trivialities, and in this case general practice would be humdrum but worthy But Dr Barber did not believe that any case was trivial, for the triumph of general practice was in sifting trivialities

General practice would always be what the individual practitioner made of it it was his own conception of his duty to his patients

Dr J D **Simpson** remarked that the responsibility borne by the general practitioner differed from that borne by his hospital colleagues He should have a special knowledge of the environment of his patients, for the treatment of a given condition varied in relation to the person's immediate circumstances Thus the doctor must be prepared to accept greater risks for the man having his "last shot" at a university scholarship than he would for a boy who was taking one part of his first M B from school at the age of 16 The question of fitness for athletics was often put to the general practitioner If called on to make a decision on behalf of the team by the captain, he must decide the risk to the patient and to the side For example one more dislocation would not do great harm to the good rugger player who had already dislocated his shoulder twice, but the side might lose him early in the game One transient loss of consciousness did not justify a diagnosis of epilepsy, and in these circumstances electro encephalography would, in nine cases out of ten, confuse the issue as would the administration of phenobarbitone "to stop any further fits" How much better and more courageous to tell the patient that "it was a faint," and to wait without giving drugs till the next attack, which might never happen Sometimes the doctor might be wrong but the number of patients he would save from fear of a disease which they had not got would amply justify his action He must, of course, tactfully stop them indulging in particularly dangerous activities

A special subject of research gave the practitioner additional incentive and interest His opportunities for research were twofold First, there was the long term collection of cases of a particular disease, for this he must keep a nosological record—a list of patients who had had the disease When planning an investigation, he should first seek a statistician's advice Secondly, there was the recognition of clinical syndromes during epidemics

In summary, the general practitioner must be expert in the environment of his patients, and he should not fear to accept responsibility which will save his patients anxiety

Dr C M **Billington** thought there was no good in going back to the family doctor of 1884, who had little armament except love, it was necessary to look at what the general practitioner could do to produce health, either on his own or in a team This was a new concept

Dr E P **Scott** recalled that Mackenzie did his work on digitalis when a general practitioner at Burnley He was sorry that the expression "family doctor" had gone out It would have been a pity if the artist had labelled that famous picture "The General Practitioner" instead of "The Doctor"—and much worse if he had made it, as it might become, "General Medical Operative"

Dr E B **Rayner** said that when the general practitioner passed his patient on to the hospital service he too often did not—for reasons well known—pass on sufficient information

Dr **Laurence Dulake** regarded the general practitioner as the only "proper doctor"—all the rest were incomplete doctors The object of general practice, as he saw it, was to give people another chance An old doctor had told him that G P s fell into two classes—the "pooh poohers" and the "tut tutters" Dr Dulake did not hold with "tut tutting" out loud, but he would prefer to know, by examination, whether a patient was epileptic or not He found that about 60% of patients suffered from gross psychological disorder Linkage with psychiatrists in the neighbourhood was useful for the general practitioner

Dr D M **Hughes** thought that general practice was the practice of being a "doctor" A specialist was not a doctor in the traditional sense, he wanted to practise medicine as an intellectual pursuit and incidentally to help the patient and doctor Dr Hughes was not saying that one concept was higher than the other, but the two were different

Dr **Lindsey Batten** also pointed out that general practitioners were the only *people* in the profession who looked after the whole patient He did not think this could be done by *teams* it had essentially to be done by the individual One job of the general practitioner was to explain to the patient what was the matter with him, a complaint about hospitals was that the patient often came out without ever learning the nature of his illness The general practitioner had not only to introduce the specialist to his patient but in a sense to protect the patient from the specialist

Dr M C **Andrews** limited as far as possible, the number of consultants he called in so that they got to know not only the patients but himself and his attitude to the patients

THE LANCET

Peace at Home

LOOKING back over the past five years, we may agree that the main achievement of the Labour Government has been to redistribute the national wealth without using or evoking violence The war, which made it necessary to increase the social rights of the ordinary citizen, created also the feeling of comradeship that has permitted an increase by consent Those who were relatively rich, whether in possessions or position, have yielded much with a good grace because they too have thought it right that, in a people so united in adversity, every family should henceforth be sure of help against illness or poverty Through social security an ideal has been largely realised, and this country no longer consists of DISRAELI's two nations Yet somehow we lack a corresponding sense of success, of coöperation, of responsibility, and of hope With world peace in deepening peril our rulers may well find it hard to inspire such hope and unite us in strenuous work to raise the quality of our national life But sometimes it seems that everyone now sets too little store by unity, indeed that, reversing the usual practice, we engage in controversy at home to take our minds off what is happening abroad

These generalisations can be applied to the particular case of the National Health Service We could and should be proud that in troubled times the medical services of this country have not only been maintained but in places already extended, and doctors who have suffered in the process should at least derive some comfort from the knowledge that vast numbers of people are thankful to be able to get medical care without direct payment Yet few of those who work the service feel that they are taking part in a great new venture in which thought and endeavour will bring steady improvement Social historians will probably attribute the establishment of the N H S to a masterly mixture of courage and compromise, of planning and improvisation, and they will be astonished that so much was done so fast But those of us who are living through the social history are conscious more of the soluble problems that remain unsolved, of the faults that remain unrectified, of the limits set on progress, and of the absence of coherent policy Delays would be tolerated if we were sure of every question being considered on its merits after full examination of the facts by those most likely to understand them, but clearly this ideal state of affairs has not been reached Where all should be loyally pursuing one aim—to give the public the most useful service that can be devised for the available money—we have instead an atmosphere of conflict, with somewhat arbitrary decisions on one side and a tendency to threats on the other Moreover the conflict is acquiring a political flavour, for one outcome—and cause—of the maladjustment between the British Medical Association and the Minister of Health is that the chief representative organisation of the profession appears to have abandoned its political neutrality, and thereby prejudiced its status in negotiation Everyone knows that frank expression of differing opinions is a necessary preliminary to decisions, and it is useless to pretend that differences do not exist; but if the public is to be served, and medicine to be advanced, the Ministry and the profession must work together to that end, and not in general opposition to one another If it is to acquire the unity it needs, the health service must be kept, as far as possible, out of party politics

As far as possible What does this mean? One must admit at once that a service of this kind has to operate within the bounds of political decisions First and most obviously there is the Chancellor's decision on what sum can be found to finance it But there are also many others The proposal, for example, to charge patients for board and lodging in hospital is really a proposal to collect more money from the public for the benefit of the service, and an additional levy of this kind could be imposed only if the Government thought fit Again, it may seem to the medical profession that the large sums now spent on providing spectacles and dentures could more profitably be used elsewhere—for instance, in enlarging specialist services But in the last resort it is the function of the Minister, not of the profession, to decide what the public shall be given, and he would be within his rights if he formed the opinion that actually people gain more from being able to bite their food, or read their newspaper (though possibly Mr BEVAN would not choose this example) than from having a ventriculography or even a thoracoplasty in their last illness Equally we should be entitled to reply that if the service does not employ diagnostic and therapeutic methods of the latest type, and provide for their development, medicine in this country will stagnate, and in the end the public will be the losers Likewise we can object to the demand for dentures being met at the cost of a preventive dental service for children The truth is that the Minister's decisions, though political in the sense that they are not technical, should be based not on what the public wants but on what it *needs*—taking a long view Though he must bear the responsibility for the decisions, and present them to the Cabinet and the country, he ought to have the help of a body charged with forming and continually reviewing the policy on which the service shall develop, the priorities to be given to its various projects, and the effect of one decision on another Mr BEVAN has a remarkable knowledge of the service and has championed it successfully against the Treasury in a way that a less powerful Minister could never have done The Ministry deserves credit for accomplishing an administrative transformation of quite appalling complexity But the Minister and civil servants, if left to themselves, may well put public demands before public needs, and they are tempted to solve their urgent problems empirically without reference to a general plan The recent memorandum on registrars is an example of an important decision taken without enough discussion of its consequences, not least of which has been the alienation of some of the service's strongest supporters and keenest workers such are well done They will be useful to research workers on alkaloids, and can be cordially recommended to advanced students, being rich in accounts of interesting reactions and of the ingenious methods by which the structures of alkaloids are being determined

The Health of the People

S Leff, M D , medical officer of health for Willesden London Gollancz 1950 Pp 288 12*s* 6*d*

"This," says the wrapper, "is in effect a comprehensive survey of all aspects of the health, living and working conditions and medical services of the people of this country " But Dr Leff's conception of "The People " is something much less than the whole population , it is rather an economic class, coterminous, at widest, with the wage-earners and their dependants and contrasted throughout the book with the "well to-do," with whom they are seen to be in constant and inevitable opposition The health with which the book is concerned is that neutral state for which we make Ministers and medical officers responsible , good health and the healthy find little mention Dr Leff's real subject is rather the relation of the community to those of its citizens who, for one cause or another, need material assistance He shows very convincingly how lamentably we always have fallen short of supplying the needs of the sick, the poor, the old, the crippled, and, in some respects, the wage earners of our population For any who may believe that we have, or have nearly, provided for our dependants, especially for the sick in mind or body, this book should prove a valuable corrective , and it will also administer a cold douche to the *laudator temporis acti* But not all will feel that the cupidity of the "well-to-do" and the existence of vested interests are almost the sole cause Are not apathy, dullness of soul, reluctance to face formidable difficulties, and plain laziness—qualities in which no class has a monopoly or even a priority—at least as much to blame ? Dr Leff believes that our present National Health Service may fail to supply the People's needs because of "centralised bureaucracy in Whitehall and bureaucracy of technicians [i e , 'doctors and specialists '] at all levels of administration " His remedy is reform and revival of local government and the transfer of administrative power from the "technicians" and other appointed members to the "elected representatives of the People " The book would be more persuasive if it were less bitter, and harped less on one string

Der Film als Experiment und Heilmethode

Jaromir Lhotsky , Prof O Pötzl Vienna Maudrich. 1950 Pp 136 Ö S 30

The title arouses expectations which the contents do not satisfy The first two chapters are concerned with the psychology of films and "the problem of film-experience " The theoretical requirements for experimental application of films to scientific study are then very briefly stated, a chapter on objective methods of recording psychological phenomena is interpolated, and a short account is given of some technical points in cinematography, using 16 mm film The study of normal and abnormal psychology by means of the film is then systematically reviewed, but too cursorily to be of value , even the investigations which Dr Lhotsky himself made in mental hospitals are little more than listed Allusion is also made to the possibilities of applying the film to vocational selection and "lie-detecting," and the lines of possible development are sketched out The book is suggestive rather than informative

A lengthy appendix, by Professor Pötzl, contains an essay which he wrote in 1938 on the comparison of films with dreams He examines the vivid optic hallucinations of drunkards, which are seen in three dimensions in delirium tremens, whereas when they occur in acute alcoholic psychosis they are two-dimensional Pötzl carried out tachistoscopic experiments on a patient with this condition who had had, years before, a hemianopsia from cerebral syphilis it was possible to excite a series of hallucinatory pictures in the section of the visual field previously affected by the hemianopsia A number of these tachistoscopic experiments are described, in which dream pictures were evoked , and Professor Pötzl analyses, in an intricate and somewhat obscure argument, the cerebral determinants of the movements and time relations evident in these visual phenomena

Traité du pneumothorax extra-pleural

P le Foyer and E Delbecq with the collaboration of M Bertheau, M Bidermann, A Garnier, L Giaccardo, and G Larraud Paris Doin 1950 Pp 367 Fr 2500

In this monograph the authors consider all aspects of extrapleural pneumothorax, emphasising perhaps the surgical side, and the complications, rather than the problems of selection, though these are certainly not ignored It is a comprehensive and thorough work freely illustrated, and for those who do not read French with much accuracy there is a summary in English at the end of each chapter or section The names and experience of the two authors are sufficient evidence that this is an authoritative work, though naturally it contains views with which other experts would not always agree

A Short Textbook of Radiotherapy for Technicians and Students

J Walter, B M , M.R C P , D M.R.E , consultant radiotherapist and deputy medical director, Sheffield Nation Centre for Radiotherapy , H Miller, M.A., PH.D. F INST.P , physicist to the centre London J & A Churchill 1950 Pp 444 28*s*

This small textbook fulfils its purpose and can b recommended to all radiographers who intend *to sit fo* the Society of Radiographers' certificate *in radiotherapy* The physical section gives a lucid account of those parts of a difficult subject which all who use X rays and radioactive substances must not only learn but understand A short biological and pathological introduction leads to the methods used in treatment Here it has been more difficult to select suitable material, but on the whole the choice and presentation is good The initiative of the authors will be welcomed by those who have to teach therapy to radiographers

---

Principles of Medical Statistics (London *The Lancet* Pp 282 10*s* 6*d*)—The fifth edition of Prof A Bradford Hill's book differs in only one major respect from the fourth In response to a real need for worked examples of the statistical methods outlined in the main text, he has included a number of questions against which the student can test his understanding The model answers, which are given in some detail, considerably enhance the didactic value of this addition to a book which has become the standard introductory text on statistics for the medical investigator

Common Skin Diseases (9th ed London H K. Lewis. 1950 Pp 505 25*s*)—The new edition of this standard textbook by Dr A. C Roxburgh contains much new material on anti histamine drugs, dimercaprol, mepacrine, penicillin dermatitis, and other topics Work on penicillin and calciferol has been brought up to date, and a note has been added on the use of streptomycin in intractable lupus vulgaris. The book has been thoroughly revised, and the illustrations—some coloured, many plain, and all good—have been augmented by three new ones

Collected Papers by Sigmund Freud (Vol 5 London Hogarth Press 1950 Pp 396 25*s*)—Edited by James Strachey these are miscellaneous papers published between 1888 and 1938 The piety of psycho analysts has ensured that everything written by the founder of their branch of knowledge should be available, in the original German and in translation It is remarkable that the rather fugitive papers collected in this volume contain so much that is not only of historical interest but enlarges our knowledge of Freud's outlook and illuminates some obscure corners of psycho analytic theory Besides encyclopædia articles and other concise expositions, there are random notes, little more than occasional jottings, and considered statements of a problem (as in paper 30, on the termination of analysis) Freud, we are told, once said to an intimate I am not a Freudian myself ' The reader often has cause in reading these papers, to recognise Freud's freedom from the pedantry and conceit sometimes disclosed in the writings of his followers In this final volume of the canon he emerges once more as a man of lofty mind with a constant singleness of purpose in all his studies and reflections

THE LANCET

LONDON SATURDAY, JAN 6, 1951

Peace at Home

Looking back over the past five years, we may agree that the main achievement of the Labour Government has been to redistribute the national wealth without using or evoking violence. The war, which made it necessary to increase the social rights of the ordinary citizen, created also the feeling of comradeship that has permitted an increase by consent. Those who were relatively rich, whether in possessions or position, have yielded much with a good grace because they too have thought it right that, in a people so united in adversity, every family should henceforth be sure of help against illness or poverty. Through social security an ideal has been largely realised, and this country no longer consists of Disraeli's two nations. Yet somehow we lack a corresponding sense of success, of coöperation, of responsibility, and of hope. With world peace in deepening peril our rulers may well find it hard to inspire such hope and unite us in strenuous work to raise the quality of our national life. But sometimes it seems that everyone now sets too little store by unity; indeed that, reversing the usual practice, we engage in controversy at home to take our minds off what is happening abroad.

These generalisations can be applied to the particular case of the National Health Service. We could and should be proud that in troubled times the medical services of this country have not only been maintained but in places already extended; and doctors who have suffered in the process should at least derive some comfort from the knowledge that vast numbers of people are thankful to be able to get medical care without direct payment. Yet few of those who work the service feel that they are taking part in a great new venture in which thought and endeavour will bring steady improvement. Social historians will probably attribute the establishment of the N.H.S. to a masterly mixture of courage and compromise, of planning and improvisation; and they will be astonished that so much was done so fast. But those of us who are living through the social history are conscious more of the soluble problems that remain unsolved, of the faults that remain unrectified, of the limits set on progress, and of the absence of coherent policy. Delays would be tolerated if we were sure of every question being considered on its merits after full examination of the facts by those most likely to understand them; but clearly this ideal state of affairs has not been reached. Where all should be loyally pursuing one aim—to give the public the most useful service that can be devised for the available money—we have instead an atmosphere of conflict, with somewhat arbitrary decisions on one side and a tendency to threats on the other. Moreover the conflict is acquiring a political flavour; for one outcome—and cause—of the maladjustment between the British Medical Association and the Minister of Health is that the chief representative organisation of the profession appears to have abandoned its political neutrality, and thereby prejudiced its status in negotiation. Everyone knows that frank expression of differing opinions is a necessary preliminary to decisions, and it is useless to pretend that differences do not exist; but if the public is to be served, and medicine to be advanced, the Ministry and the profession must work together to that end, and not in general opposition to one another. If it is to acquire the unity it needs, the health service must be kept, as far as possible, out of party politics.

As far as possible. What does this mean? One must admit at once that a service of this kind has to operate within the bounds of political decisions. First and most obviously there is the Chancellor's decision on what sum can be found to finance it. But there are also many others. The proposal, for example, to charge patients for board and lodging in hospital is really a proposal to collect more money from the public for the benefit of the service, and an additional levy of this kind could be imposed only if the Government thought fit. Again, it may seem to the medical profession that the large sums now spent on providing spectacles and dentures could more profitably be used elsewhere—for instance, in enlarging specialist services. But in the last resort it is the function of the Minister, not of the profession, to decide what the public shall be given; and he would be within his rights if he formed the opinion that actually people gain more from being able to bite their food, or read their newspaper (though possibly Mr Bevan would not choose this example) than from having a ventriculography or even a thoracoplasty in their last illness. Equally we should be entitled to reply that if the service does not employ diagnostic and therapeutic methods of the latest type, and provide for their development, medicine in this country will stagnate, and in the end the public will be the losers. Likewise we can object to the demand for dentures being met at the cost of a preventive dental service for children. The truth is that the Minister's decisions, though political in the sense that they are not technical, should be based not on what the public wants but on what it *needs*—taking a long view. Though he must bear the responsibility for the decisions, and present them to the Cabinet and the country, he ought to have the help of a body charged with forming and continually reviewing the policy on which the service shall develop, the priorities to be given to its various projects, and the effect of one decision on another. Mr Bevan has a remarkable knowledge of the service and has championed it successfully against the Treasury in a way that a less powerful Minister could never have done. The Ministry deserves credit for accomplishing an administrative transformation of quite appalling complexity. But the Minister and civil servants, if left to themselves, may well put public demands before public needs, and they are tempted to solve their urgent problems empirically without reference to a general plan. The recent memorandum on registrars is an example of an important decision taken without enough discussion of its consequences, not least of which has been the alienation of some of the service's strongest supporters and keenest workers.

such are well done They will be useful to research workers on alkaloids, and can be cordially recommended to advanced students, being rich in accounts of interesting reactions and of the ingenious methods by which the structures of alkaloids are being determined

The Health of the People

S LEFF, M D, medical officer of health for Willesden London Gollancz 1950 Pp 288 12*s* 6*d*

"THIS," says the wrapper, "is in effect a comprehensive survey of all aspects of the health, living and working conditions and medical services of the people of this country" But Dr Leff's conception of "The People" is something much less than the whole population, it is rather an economic class, coterminous, at widest, with the wage earners and their dependants and contrasted throughout the book with the "well-to-do," with whom they are seen to be in constant and inevitable opposition The health with which the book is concerned is that neutral state for which we make Ministers and medical officers responsible, good health and the healthy find little mention Dr Leff's real subject is rather the relation of the community to those of its citizens who, for one cause or another, need material assistance He shows very convincingly how lamentably we always have fallen short of supplying the needs of the sick, the poor, the old, the crippled, and, in some respects, the wage earners of our population For any who may believe that we have, or have nearly, provided for our dependants, especially for the sick in mind or body, this book should prove a valuable corrective, and it will also administer a cold douche to the *laudator temporis acti* But not all will feel that the cupidity of the "well-to do" and the existence of vested interests are almost the sole cause Are not apathy, dullness of soul, reluctance to face formidable difficulties, and plain laziness—qualities in which no class has a monopoly or even a priority—at least as much to blame? Dr Leff believes that our present National Health Service may fail to supply the People's needs because of "centralised bureaucracy in Whitehall and bureaucracy of technicians [i e, 'doctors and specialists'] at all levels of administration" His remedy is reform and revival of local government and the transfer of administrative power from the "technicians" and other appointed members to the "elected representatives of the People" The book would be more persuasive if it were less bitter and harped less on one string

Der Film als Experiment und Heilmethode

JAROMIR LHOTSKY, Prof O PÖTZL Vienna Maudrich 1950 Pp 136 ÖS 30

THE title arouses expectations which the contents do not satisfy The first two chapters are concerned with the psychology of films and "the problem of film-experience" The theoretical requirements for experimental application of films to scientific study are then very briefly stated, a chapter on objective methods of recording psychological phenomena is interpolated, and a short account is given of some technical points in cinematography, using 16 mm film The study of normal and abnormal psychology by means of the film is then systematically reviewed, but too cursorily to be of value, even the investigations which Dr Lhotsky himself made in mental hospitals are little more than listed Allusion is also made to the possibilities of applying the film to vocational selection and "lie-detecting," and the lines of possible development are sketched out The book is suggestive rather than informative

A lengthy appendix, by Professor Pötzl, contains an essay which he wrote in 1938 on the comparison of films with dreams He examines the vivid optic hallucinations of drunkards, which are seen in three dimensions in delirium tremens, whereas when they occur in acute alcoholic psychosis they are two-dimensional Pötzl carried out tachistoscopic experiments on a patient with this condition, who had had, years before, a hemianopsia from cerebral syphilis it was possible to excite a series of hallucinatory pictures in the section of the visual field previously affected by the hemianopsia A number of these tachistoscopic experiments are described, in which dream pictures were evoked, and Professor Pötzl analyses, in an intricate and somewhat obscure argument, the cerebral determinants of the movements and time relations evident in these visual phenomena

Traité du pneumothorax extra-pleural

P LE FOYER and E DELBECQ with the collaboration of M Bertheau, M Bidermann, A Garnier, L Giaccardo, and G Larraud Paris Doin 1950 Pp 367 Fr 2500

IN this monograph the authors consider all aspects of extrapleural pneumothorax, emphasising perhaps the surgical side, and the complications, rather than the problems of selection, though these are certainly not ignored It is a comprehensive and thorough work freely illustrated, and for those who do not read French with much accuracy there is a summary in English at the end of each chapter or section The names and experience of the two authors are sufficient evidence that this is an authoritative work, though naturally it contains views with which other experts would not always agree

A Short Textbook of Radiotherapy for Technicians and Students

J WALTER, B M, M.R C P, D.M R E, consultant radiotherapist and deputy medical director, Sheffield National Centre for Radiotherapy, H MILLER, M A., PH.D., F INST P, physicist to the centre London J & A. Churchill 1950 Pp 444 28*s*

THIS small textbook fulfils its purpose and can be recommended to all radiographers who intend to sit for the Society of Radiographers' certificate in radiotherapy The physical section gives a lucid account of those parts of a difficult subject which all who use X rays and radioactive substances must not only learn but understand A short biological and pathological introduction leads to the methods used in treatment Here it has been more difficult to select suitable material, but on the whole the choice and presentation is good The initiative of the authors will be welcomed by those who have to teach therapy to radiographers

---

Principles of Medical Statistics (London *The Lancet* Pp 282 10*s* 6*d*)—The fifth edition of Prof A Bradford Hill's book differs in only one major respect from the fourth In response to a real need for worked examples of the statistical methods outlined in the main text, he has included a number of questions against which the student can test his understanding The model answers, which are given in some detail, considerably enhance the didactic value of this addition to a book which has become the standard introductory text on statistics for the medical investigator

Common Skin Diseases (9th ed London H K Lewis. 1950 Pp 505 25*s*)—The new edition of this standard textbook by Dr A. C Roxburgh contains much new material on anti histamine drugs, dimercaprol, mepacrine, penicillin dermatitis, and other topics Work on penicillin and calciferol has been brought up to date, and a note has been added on the use of streptomycin in intractable lupus vulgaris The book has been thoroughly revised, and the illustrations—some coloured, many plain, and all good—have been augmented by three new ones

Collected Papers by Sigmund Freud (Vol 5 London Hogarth Press 1950 Pp 396 25*s*)—Edited by James Strachey these are miscellaneous papers published between 1888 and 1938 The piety of psycho analysts has ensured that everything written by the founder of their branch of knowledge should be available, in the original German and in translation It is remarkable that the rather fugitive papers collected in this volume contain so much that is not only of historical interest but enlarges our knowledge of Freud's outlook and illuminates some obscure corners of psycho analytic theory Besides encyclopædia articles and other concise expositions, there are random notes, little more than occasional jottings, and considered statements of a problem (as in paper 30, on the termination of analysis) Freud, we are told once said to an intimate 'I am not a Freudian myself' The reader often has cause in reading these papers, to recognise Freud's freedom from the pedantry and conceit sometimes disclosed in the writings of his followers In this final volume of the canon he emerges once more as a man of lofty mind with a constant singleness of purpose in all his studies and reflections possible by emptying the stomach and then keeping it empty to prevent any further leak from the perforation and so allow it to seal naturally. If such a course can be shown to be no less successful than operation its advantages are great. Operation should always be avoided if other measures will suffice. Quite apart from fatalities, abdominal operations may cause such complications as incisional hernia (of which "burst abdomen" may be reckoned a fulminating variety) and intestinal obstruction due to adhesions, to say nothing of the inconvenience caused to the surgeon performing a subsequent operation by the scarred abdominal wall and peritoneal adhesions. There is, however, one advantage that a non-operative method might at first sight seem to offer but which the aspiration treatment of peptic ulcer denies us. An experienced surgeon must be at hand throughout the management of these cases and particularly in the first six hours, for in certain circumstances operation must after all be undertaken without further delay. The folly of entrusting the conservative treatment to an inexperienced surgeon is emphasised by STEAD, whose article also appears in this issue; he believes that an inexperienced surgeon will do better to operate provided a good anæsthetist is available.

There are serious objections to this new method of treatment. One of the weightiest is the possibility of mistaking the diagnosis and so failing to operate on cases, such as acute appendicitis, in which early operation is essential. TAYLOR claims that his experience silences this criticism, for he has had only 4 cases in which the original diagnosis of perforated peptic ulcer was later proved wrong. In 2 of these cases the conditions turned out to be of a sort prohibiting or at least not requiring surgery, but in the other 2 a necessary operation was slightly delayed. It may well be, as TAYLOR says, that in these 2 cases the delay in operation made no difference, but few surgeons will feel entirely reassured that on other occasions similar cases might not turn out worse. With the aspiration method the position of the patient seems rather precarious. Like the diver on the bottom of the sea, his life depends utterly on an uninterrupted flow through a long flexible tube. The difficulties of ensuring that aspiration is continuously effective are serious if surmountable; and most surgeons would prefer the single, final stopping of the leak which only operation can secure. Another serious objection—not mentioned by TAYLOR or STEAD—is the necessity of keeping the patient in bed and relatively still for several days while the perforation is sealing. The importance of early mobilisation is now generally recognised, and it must be noted that one of TAYLOR's early cases died of pulmonary embolism. In studying the results of conservative treatment and comparing them with operative results, a serious difficulty must be faced. In an operative series every diagnosis is established by operation; in a non-operative series the diagnosis rests on radiological and clinical findings. Positive radiological evidence can usually be accepted as conclusive; but sometimes this evidence is uncertain; and in about one-third of the cases it is negative. It is true that in many of these cases the presence of an ulcer is subsequently proved, and in some an operation may later show that perforation has taken place; yet in an important proportion of the cases proof of perforation is lacking; and we feel that this somewhat reduces the significance of the mortality figures. The gross mortality of TAYLOR's 101 cases was a fraction under 11%. From other sources he has collected a further 454 cases, and the mortality for the whole series is just under 8%, which certainly compares favourably with most published figures for operative treatment. By analysing the mortality figures and excluding cases moribund on admission and those with other diseases which have contributed to the fatal issue, a net mortality percentage much more favourable to the conservative method may be arrived at; but such adjusted figures are not acceptable. In the contest between rival treatments the prize can be awarded only to the competitor who wins from scratch. The comparisons, moreover, must be contemporary, and it may be misleading to judge the results of conservative treatment against those of surgery in the years before 1945. We may say that the exponents of the conservative treatment have made a case for their method as a safe alternative to surgery, and in particular they have shown how much can be done for the patient who is too ill for operation; and great credit is due to these surgeons for their courage and vision. But they have certainly not yet proved that aspiration is better than suture.

In the last few years there has been a sharp reduction in the mortality of many different abdominal operations, and the suture of perforated peptic ulcer has shared in this improvement. In 1939 SANGSTER[3] reported 100 perforations with 24 deaths; in 1948 he reported 105 with only 4 deaths.[4] At a meeting of the surgical section of the Royal Society of Medicine on Dec. 6, Prof. DIGBY CHAMBERLAIN reported the results of 1622 cases treated during the years 1930–49. The over-all mortality was 17.9% (including the cases too ill for operation), but in the last two years the mortality was only 6% and 7%. The Central Middlesex Hospital[5] results are similar and in some ways more impressive. In the last three years 165 cases were admitted and 11 died—a gross mortality of 6.6%. Although this figure must be accepted as it stands, it is important to note that of the 155 cases operated on only 2 died. AVERY JONES and his colleagues[6] have reported a larger series from the Central Middlesex Hospital which shows how striking was the steady improvement in results over the ten years 1938–48—and this despite a great increase in the proportion of aged people. It is not possible to demonstrate conclusively what is the cause of this improvement, but there is strong evidence that antibiotics and improved anæsthesia are the main factors, with better postoperative care (including early rising) and advances in surgical technique (such as the avoidance of drainage) also helping. In this country in the past few years the general standard of emergency surgery has been raised by the presence of more surgical registrars in the hospitals, and its results have much improved because skilled anæsthetists, using modern methods including muscle relaxation, are on hand to help them. It remains very doubtful whether conservative treatment, even conducted by an experienced unit, is equally safe for the patient, and we endorse the opinion that, until the facts are clearer, it should be

To give a sense of united effort two things are necessary first, the representatives of those who work the service must join with the Ministry in forming a development policy against which any proposed action can be tested, and secondly every member of the service must know that all constructive suggestions have attention at a high level This dual need was recognised in the original scheme, when great significance was attached to the creation of a Central Health Services Council to advise the Minister[1] But unhappily the council, despite much good work by its standing committees, has so far failed to fulfil its main functions As it has made no attempt to evolve a general policy, and as its very existence is commonly forgotten, it serves neither as the mind nor as the mouthpiece of the service, though it should be both For these shortcomings there are two reasons First, the Ministry has a long record of ignoring its advisory committees, and the Central Health Services Council, modestly disclaiming a position of leadership, has been content to accept the minor, if useful, duty assigned it—that of giving technical advice on single subjects This handicap might be overcome by a more forceful disposition on the part of the council itself, but we should still be left with the second cause of failure, which depends on principles rather than personalities The reason why members of the service know little or nothing about the labours of the C H S C is that its proceedings (apart from an annual report subject to the Minister's censorship) are confidential The argument in favour of this arrangement is a strong one—namely, that if the council's meetings were public, or if it issued its opinions to the press, the Minister would never feel able to consult it on delicate subjects before a decision was reached, and might well refuse it the full information it must possess if its conclusions are to have weight Time may show that the advantages of this secrecy are being bought too dearly it might be more healthy to have a more representative and less confidential council, able to argue publicly with the Minister, so that the reasons for and against his actions would be plain to all concerned Meanwhile the least the Ministry should do is to give the fullest possible publicity to the work of the council, allowing it to issue frequent statements on the advice it has given, and sometimes to invite expressions of opinion by members of the service on subjects on which it is about to deliberate

After its inevitably shaky start, the National Health Service badly needs a period of consolidation, and one of the things to be consolidated is the morale of those who work it If a sense of confidence and purpose and hope is to be created, they must feel that it has a development policy, and that its decisions are based on that policy and on equity—not on hard bargaining, and certainly not on party politics Moreover, they must understand what the policy is, and be enabled to influence those charged with forming and reviewing it If the Minister and some of the profession's spokesmen would cease blaming each other for the imperfections of a service which is being constructed with fair success in extraordinarily difficult circumstances, there would be more time for explanation to the participants, both lay and medical, and more pride in what has been done In determining future policy, the really big issues could be faced more squarely, and we might gradually get rid of the idea that organisation is always something imposed unnecessarily on "us" by "them" The National Health Service is part of this country's endeavour to devise a way of life in which rational planning is combined with a high degree of personal freedom Such an experiment, we are rightly reminded,[1] is a daring novelty compared with the authoritarian régimes which have been customary through the ages and still dominate half the world To make it succeed we need more than peace abroad We need at home the kind of peace that is manifest in discussion without discord

Treatment of Perforated Peptic Ulcer

"THE perforation of a gastric or duodenal ulcer i one of the most serious and most overwhelming catastrophes that can befall a human being The onset o the symptoms is sudden, the course rapid, and, unles surgical measures are adopted early, the disease hasten to a fatal ending in almost every instance" Lord MOYNIHAN's striking words,[2] written a quarter of a century ago, are in the main true today except that surgical measures now have a respectable rival In the attempt to lower mortality two main *lines* may be followed elimination of the faults of operative treatment, and a trial of non operative measures

In medicine no treatment can succeed which does not act in concert with the natural curative processes of the body, and the best method of treatment will often be the one which unobtrusively supports and directs these processes and avoids violent and artificia intervention There is good evidence that the body can seal a perforation in a peptic ulcer by the deposition of fibrin and the apposition of an adjacent viscus—commonly the liver or the omentum Indeed, most posterior penetrating gastric ulcers have harmlessly perforated, the perforation being, so to speak, walled off before it occurred But even free anterior perforations not uncommonly seal themselves spontaneously and the incident can only be inferred from the finding at some subsequent operation of extensive peritoneal adhesions with perhaps encysted cellulose particles, and of an ulcer or its scar adhering to the liver or omentum In these cases the diagnosis of perforation was never made at the time it took place It is indeed often very difficult to distinguish clinically between a perforation and a severe attack of ulcer pain Many orthodox surgeons recognise this type of self sealing perforation by speaking of a "leaking" ulcer and withholding operation, also operation is regularly withheld from patients with perforated ulcers who are too ill to stand it and occasionally recovery has been reported The deliberate exploiting of the natural sealing process in patients who are fit for, and according to accepted practice urgently require, operation is of course, a different matter, but both in this country and in America conservatism of this sort now has its advocates Among the most persuasive of these is HERMON TAYLOR, who reports in this issue a series of cases treated by what he calls the aspiration method He maintains that half the operative mortality is due to complications of the operation itself, and that it is

[2] Moynihan B Abdominal Operations 1926 vol I p 223

These stimulating papers will no doubt be followed by further observations on the same lines. Already VOUREKA's work has thrown light into several obscure corners. For instance, two out of three of her variants in the end reverted, partly at any rate, to the parental pattern. It seems to follow that whatever were its characters when it emerged from the bowel, *Bact. coli* D433 has found in captivity the way of life best suited to our artificial culture media.

Annotations

BACTERIUM VERSUS VIRUS

JUST as greater fleas have lesser fleas upon their backs to bite 'em, so pathogenic bacteria going about their lawful occasions in a human host are often plagued by still smaller organisms, the virus particles of bacteriophage, which produce disease in the bacteria and (possibly, sometimes) restrict their activity enough to allow their host to recover. Attempts have been made, though without convincing success, to apply bacteriophages in therapeutics. The existence of a converse antagonism between bacterium and virus is usually ignored. Yet the late Professor Twort remarked, in a popular article, that "In test tube experiments it is easy to arrange conditions so that a bacteriophage will kill off its host, the bacterium, but . . . it is equally easy to arrange another set of conditions in which the bacterium will kill or inhibit its invading bacteriophage." This article has prompted Mrs Wooster, in our correspondence columns, to suggest the use of bacteria for controlling virus diseases.

If we take *Bacterium coli* and one of its spherical phages (T6) as examples of the proposed contestants, the dimensions of these organisms, as given by Putnam,[1] are about 2·5 × 1 μ for the bacterium and about 50 mμ for the phage. The contest will therefore be comparable if not to man against flea, at least to man against cockroach. Some pathogenic viruses would be smaller (e.g., poliomyelitis about 10 mμ) and some larger (e.g., rabies and herpes 100–150 mμ) than the coliphage. But the attractive picture of a large anthropoid bacterium chasing an elusive swarm of cockroach like viruses and finally annihilating them one by one is grossly misleading. The hope would be that the bacteria by their growth and excretions might so modify the phage's environment that its continued existence became impossible. This may be easily done in the test-tube but would be far more difficult in the body, where there are physiological mechanisms to keep the environment constant and any drastic change is likely to do more harm to the host's cells than to the virus. Most viruses, such as those of poliomyelitis or hepatitis, are embedded in the tissues, where it would be undesirable if not impossible for bacteria to pursue them. Perhaps viruses which attack cells on exposed surfaces, like herpes or the viruses causing respiratory infections, would be more accessible; but a further difficulty would be that the virus particles live and multiply *inside the cells* and exist outside only in the brief periods of passing from one cell to another. Invasion of the tissue cells by bacteria, even if they come as well meaning scavengers, is not a contingency that anyone will contemplate with equanimity.

However, before we condemn the proposal out of hand, we should perhaps recall how ridiculous it would have seemed, not many years ago, to enlist the help of green moulds in combating puerperal fever or pneumonia; yet *Penicillium notatum* was soon to be our most valued ally. We in England sometimes accuse our American cousins of allowing enterprise to outstrip judgment—of wasting too much time, effort, and money in exploring fool ideas that any sensible Englishman could have told at the start were unsound and impracticable. But now and again some fool idea, British or American, leads to a brilliant discovery; and the sensible Englishman is left to ponder whether his vaunted critical faculty is really such a reliable guide after all.

SOME TUBERCULOSIS FIGURES

To say we are neglecting the tuberculous is to pluck monotonously at a single string; possibly we can appreciate the note more fully by attending to its overtones. Dr F. J. W. Miller,[1] bringing up to date his figures already published,[2] reports that, in Newcastle upon Tyne in the ten years 1939–49, tuberculosis was the greatest single cause of death in childhood; that deaths of children formed almost 10% of the total mortality from this disease; and that tuberculosis is responsible for nearly a quarter of all deaths between the ages of one and fifteen years. This might be less serious than it sounds if the Newcastle death rate from tuberculosis was low; but it is high compared with that of the country as a whole, having been, in 1949, 75 per 100,000 population for respiratory tuberculosis—against less than 50 for England and Wales. Dr Miller illustrates the undue loss of children by comparing the figures for Newcastle (population 270,000) with those of Ealing and Acton (population 212,000): in Newcastle, in 1942–45 inclusive, 1177 people died of tuberculosis, 130 of them being children; in Ealing and Acton only 450 people died, of whom 18 were children—giving respective rates of 48 children and 8 children per 100,000 population. Moreover the death rate in Newcastle, as compared with *such other large cities as Birmingham and Manchester*, is especially high among children of school age. Dr Miller infers that the high childhood mortality means the presence of a large number of infective adults in this overcrowded city.

In Glasgow the picture is possibly more sombre still. Dr Stuart Laidlaw[3] notes that the number of new cases of pulmonary tuberculosis notified in 1949 was 2829—the highest figure recorded since 1910—and that 540 (19%) of those affected were children under the age of fifteen. There were, moreover, 12,000 people on the tuberculosis register—3000 more than before the war. Again overcrowding must be a potent factor in the spread of the disease, for "more than half the families in Glasgow are living in one or two apartment houses." What life in such conditions means, in terms of proximity, is illustrated in the Newcastle report, where the spread of an ordinary respiratory infection through a tenement is described:

> In this house rooms were let to 7 families, who combined to make a total of 13 adults, 6 children aged two to five, and 3 infants. A baby living in an attic with her parents developed pneumonia; four weeks later her mother—much given to visiting her neighbours—developed a cold. At the same time a three-year-old on the ground floor developed bronchitis, while a few days later her infant sister had pneumonia. A family of 4 on the same floor all developed respiratory illness and soon afterwards another baby in the house developed pneumonia, while her mother followed suit with a sharp cold.

It is not difficult to apply the moral of this story to a more serious infection. The point is brought home even more forcibly by Dr Laidlaw's study of the home conditions of 2674 Glasgow patients with pulmonary tuberculosis: 1300 of these—nearly half—shared their beds with others; only 444 had a bed to themselves, and only 930—just over a third—had a room to themselves. Domiciliary treatment can hardly hope to succeed in regarded as an experimental method to be left to those who are making a trial, with full knowledge of the risks, under entirely favourable conditions

[3] Annual Report of the Medical Officer of Health for 1949, Glasgow. Pp. 302.

The successful suture or sealing of a perforation is often not the end of the story According to ILLINGWORTH et al,[7] within one year 40% relapse (20% severely), and 70% relapse (50% severely) within five years Moreover hæmorrhage shortly after perforation is an important factor in the immediate mortality Another serious possibility[8] is the mistaking of perforated carcinoma for a simple ulcer (the distinction may be very difficult to recognise) or the development of carcinoma in a simple ulcer after perforation The difficulty of diagnosing carcinoma at an operation for perforated ulcer suggests that the majority of carcinomas which perforate are small and have not produced metastases, and are therefore resectable In such cases postoperative (or post-aspiration) investigations may not suggest the diagnosis of carcinoma, and the dreadful truth will reveal itself too late These considerations raise again the question of gastrectomy as the immediate treatment of perforation For years eminent Continental surgeons have advocated this procedure, but British surgeons have not been convinced Now that the mortalities of gastrectomy and of suture for perforated ulcer have dropped so low, gastrectomy for perforation should perhaps be reconsidered, for it could prevent most of the continued disability from chronic ulcer and some of the deaths from carcinoma

Bacterial Oddities Produced By Chloramphenicol

ANTIBIOTICS sometimes have odd effects on the shape, size, and cultural characters of bacteria in vitro In this issue, Dr VOUREKA, of Athens, working at St Mary's Hospital, Paddington, describes how her interest in these bizarre forms was aroused by the strange behaviour of urinary bacteria from patients under treatment with chloramphenicol After a few days of this treatment the urine appeared to be sterile, but if the drug was continued the *Ps pyocyanea* and *Bact coli* previously present reappeared in cultures swollen and distorted, producing colony forms widely different from those seen when they were first isolated Similar morphological oddities have been observed in cultures of other organisms under the action of other antibiotics, and two of the many explanations put forward[9] are (1) that they are bacterial cells which have lost their ability to divide though retaining their power to grow, and (2) that the antibiotic has interfered with the formation of the bacterial cell wall but otherwise has allowed growth to proceed

In her second paper VOUREKA describes in vitro experiments with *Bact coli* D433, done with the aim of elucidating these observations Cultivation in broth plus chloramphenicol alone produced bizarrely distorted organisms, but most of their colonies were normal in appearance When a specific antiserum and chloramphenicol were added to the culture medium the grotesques became still more varied, and pairs or chains of coccal forms were now seen besides the swollen and misshapen ones Growth was always poor and sometimes invisible, and subcultures on solid media (without antiserum or chloramphenicol) gave a scanty growth distinguished by at least three small colony forms bearing no resemblance to the parent strain All these exhibited a remarkable stability in up to 200 further subcultures, though there seemed to be an increasing tendency for the colonies to revert to their original size and shape

The bacterial variation following exposure to antibiotics which has received most attention, because of its practical implications, is the acquisition of drug resistance This is now generally looked on not as a mutation but as an effect of the selectiv survival of the most resistant members of the origin population Since high natural drug-resistance pr sumably depends on some metabolic peculiarity, is not surprising that the hyper-resistant organism occasionally possess minor aberrations in oth characters[10] It is not easy to explain why some these artificially produced resistant strains retai their resistance through multiple subcultures in medium free from antibiotic, whereas some do not VOUREKA's grotesques differ from the original strain in other features besides shape, size, and colony form and they retain these differences for many generations Serologically they are almost but not quite identica with their parent They have lost their virulence fo mice but have acquired the ability to ferment som sugars Their resistance to other inimical substance —penicillin and potassium tellurite—has changed, bu the changes are neither constant nor rational Mos surprising of all, far from being less sensitive t chloramphenicol than their parent they are equall or more sensitive It is difficult to think that change like these have arisen by the selection of strain better able to withstand the adversity of life wit chloramphenicol VOUREKA ascribes the changes t a true mutation, and though this must be only guess it is a not unreasonable one Most of wha we know about bacterial inheritance has been see through several layers of glass, very darkly, bu there must be some part of the bacterial cell housin genes that determine its inherited characters In hostile but not quite lethal environment it may b possible to effect a change in the genes which wi alter the characters of the organism for man generations Botanists accept as a matter of cours the multiplication of genes known as polyploid effected by the action of colchicine—there was eve a chance at one time that the production of penicilli by *P notatum* could be increased in this way—an similar natural sports, usually sterile, are known a high in the animal kingdom as the *mollusca* Perhap these mutations, if they are such, are commoner tha we think Every day uncountable numbers o bacteria must be brought near to death from pheno poisoning, but few bacteriologists examine the survivors It may be that such variants are more ofte seen among parasitic organisms—there is certainl wide variation in the colonial forms of *Bact col* recovered in a routine laboratory

The problem of serum neuritis became more complicated during the late war when a number of cases were reported Thus from the Middle East Burnard and Fox[6] and Spillane[7] recorded the condition (under the name of localised neuritis of the shoulder girdle) as occurring without administration of serum , in his forty six cases Spillane found no time relation between the administration of vaccines or sera and the development of paralysis Weinstein[8] recorded sixteen similar cases among American military personnel , again in none of these had serum been administered within the previous three months, but all had had prophylactic injections of typhoid or typhus vaccine 1–12 weeks before the onset of the illness Parsonage and Aldren Turner[9] reported on 136 cases of the same condition, to which they gave the purely symptomatic name of neuralgic amyotrophy The record of previous inoculations was investigated in 67 of these , the number inoculated within the preceding four weeks was 11, of whom 6 had been inoculated within the previous fortnight They found however, that in no less than 66 of the 136 cases the condition had developed intercurrently in hospital Cases of neuralgic amyotrophy without any time relation to serum or vaccine administration are still occasionally seen in this country and have also been reported from Scandinavia[10] and France[11]

This condition and serum neuritis differ in several ways from anterior poliomyelitis The onset is afebrile and is not accompanied by the constitutional and meningeal symptoms of poliomyelitis , the pain at the onset is severe and localised, which is on the whole uncommon in poliomyelitis, where pain is usually more generalised even though the subsequent paralysis is localised , commonly sensation is impaired, particularly in the distribution of C5 segment , and the cerebrospinal fluid (C.S.F.) has been normal in the majority of cases where it has been examined in the acute stage The pathology and ætiology of neuralgic amyotrophy remain obscure , but the clinical picture is exactly comparable to that of serum neuritis, and probably the two disorders have a similar basic pathology Since there is a possibility that neuralgic amyotrophy may be precipitated by vaccine inoculation, care should be taken, and the C.S.F. examined, before atrophic paralysis following inoculation is attributed to anterior poliomyelitis

ON THE RECORD

THE Royal College of Physicians has published in book form the reports of its fifteen special committees which sat between 1942 and 1947 to consider a wide range of subjects of public and professional importance[12] These have already had considerable influence, and some of them should have more The one on medical education was notable as a bold effort to free the curriculum from the accretions of ages, and in general from the obsession that a doctor cannot be safely loosed on the public unless he has had lectures on every conceivable subject—though he need *understand* nothing This report was responsible for the " pre registration resident year," which is in due course to be introduced under the new Medical Act , but the college seems to have had in mind an assistant residentship, or scarcely paid post under the supervision of a senior resident , whereas nowadays the scheme is generally regarded merely as a means of ensuring that before undertaking independent practice all doctors shall hold a house appointment The report on the design of dwelling houses starts off in rather pessimistic vein, but in its latter half it proceeds to some first class social medicine Taking them all round, the reports are further evidence that the Royal College of Physicians, when it is given the chance, can rise to the occasion as a source of sound well considered advice In his introduction, Lord Moran, president from 1941 to 1950, points to its long record of service of this kind, which we hope and believe will continue and increase

DISSEMINATION OF THE MENINGOCOCCUS

IN both world wars cerebrospinal fever (meningococcal meningitis) became epidemic among recruits in Service establishments This, together with advances in the serological typing of meningococci and the advent of chemoprophylaxis, led Aycock and Mueller[1] to make a long and continuous study, from 1941 to 1945, of carrier rates in relation to the incidence of the disease in two American army establishments

Thirty years ago Glover[2] postulated a rise in the meningococcal carrier rate to 20% as a pre epidemic danger point and suspected a relation in the army between this rise and overcrowding in sleeping huts During the inter-war period, however, Dudley and Brennan[3] found that in Naval establishments persistently high carrier rates (54%) might obtain without clinical attacks , and clinical attacks occurred despite very low carrier rates Furthermore, carrier rates were as high among senior ratings with spacious quarters as among recruits whose sleeping accommodation was much inferior Early in the late war Fairbrother[4] suggested that fatigue was more important than overcrowding in predisposing to clinical attacks, especially among recruits from rural districts, whose natural immunity was likely to be low

Aycock and Mueller discount altogether the effect of overcrowding They found that the disease is fairly uniformly distributed throughout the U.S.A. during years of high and low prevalence alike Plotting of reported cases during the period 1915–48 showed an undulating curve of increases and decreases, each extending over a period of 6–11 years, with peaks in 1918, 1929, 1936, and 1943 This rhythmical variation is a continuing phenomenon, and is not due to independent seasonal epidemics, since the rhythm during the epidemic season varies with that in the inter epidemic summer months But the pattern of periodicity differs from that of such " immunising infections " of childhood as measles, chickenpox, and diphtheria With these, an epidemic is terminated by the " exhaustion of susceptibles " and recurs only when enough non immunes have once again accumulated Thus Aycock and Mueller deny that natural immunity following exposure shapes the epidemic pattern of meningococcal meningitis , season is responsible, they find, only for secondary fluctuations in the longer cyclic curve, and there is no single cause for either

Using a method for prolonging the viability of the meningococcus on nasopharyngeal swabs, similar to that described by Downie,[5] these workers have compared the carrier rate of various serological types among seasoned troops and recruits , and they suggest that the carrier-rate among the latter may represent that of the civil population—a view later supported by swabbings of Harvard medical students In the two military groups the total carrier rates and their type-composition were essentially the same, and there was no indication of the seasonal variation which obtains for clinical attacks But, whether in the army or the civilian population, type composition is not stable , the carrier-rate for one type may increase while the rates for other types are stationary or declining Aycock and Mueller believe that these changes, which are not sudden or frequent, are natural such conditions, and protection of contacts becomes a mockery The acute need for more treatment beds in Glasgow is illustrated by the statements that, in spite of the rise in incidence, the number of cases under treatment in hospitals and sanatoria was no greater than in 1948, and that though there were only 351 deaths in institutions, as compared with 486 in 1948, this was mainly because advanced chronic cases could not gain admission They were at home, of course, sometimes infecting others

These two reports remind us tellingly that tuberculosis is a social disease In overcrowded cities we can only hope to check its widening course by providing more houses or more beds—but preferably both

STERILISATION LAWS

THE sterilisation of certain classes of mentally or eugenically defective patients, which recurs, along with euthanasia, as a subject for ethicomedical debate in England, has been practised in the State of North Carolina since 1933, when the General Assembly regularised an earlier measure which had been ruled unconstitutional on appeal Woodside gives an account [1] of this experiment in action which is likely to interest both the opponents and the advocates of eugenic sterilisation

The North Carolina sterilisation law is a fair specimen of American State eugenic legislation Under it, sterilisation proceedings may be initiated by the head of any State penal or charitable institution, or by the county senior welfare officer, and action is mandatory upon these officials if a written request is presented by the next of kin or guardian of the patient The Eugenics Board, which administers the hearing of petitions for sterilisation, may act only in cases of mental disorder, feeblemindedness, or epilepsy (Voluntary sterilisation at the request of the normal patient is left to the discretion of the surgeon and has nothing to do with the eugenic laws) Detailed medical and social reports and the sworn consent of the patient, unless he or she is a minor, an inmate of a State mental institution, or of unsound mind ("certified"), are required No other eugenic or social reasons are recognised Failing the consent of the relatives, action can proceed at the discretion of the board, but with full rights of appeal to the superior court of the county, and only minors or the insane can be sterilised without their own consent Appeal to the courts, while it is the normal democratic safeguard, is possibly less adequate than Woodside suggests, since the appellants are almost uniformly feebleminded and underprivileged, but, as she points out, the use or abuse of the law depends on the spirit in which it is carried out, and the North Carolina law has not so far produced any flagrant injustice In this respect it is less open to criticism than other American State laws which prescribe compulsory sterilisation for delinquents and sexual deviants, sometimes without reference either to the non-hereditary nature of the complaint or to the emotional attitudes of courts

Since 1907, when Indiana introduced a sterilisation law, 49,207 sterilisations have taken place in the United States, 2152 being in North Carolina Most of these cases were among the group likely to benefit most, the feebleminded To the high grade female defective, incapable (as is often the case) of learning or maintaining contraception, sterilisation may mean a freer life, since the administrative argument for inpatient confinement is removed, while for the community the eugenic benefit is evident Woodside cites work done by herself and Eliot Slater confirming the tendency to consortive mating in the unintelligent, and with defectives this is even more prominent While many defectives are incapable, both biologically and psychologically, of safe parenthood, they may none the less be capable of proving happy and affectionate wives, and it is doubtful whether the restriction of rights involved in voluntary sterilisation is anything like as grave as that implied by restrictions on the "emotional contacts of the female patient" on licence from English institutions

One extraordinary feature of the North Carolina scheme is that only institutions with surgical facilities can really apply it at their discretion, for no funds exist for extramural operations On the wider issue, Woodside describes the possibilities of voluntary sterilisation in relation to current attitudes and prejudices in the public North Carolina has remarkably advanced provisions for contraceptive instruction, but many patients seem unable to take full advantage of them and benefit greatly by sterilisation once its nature and purpose, together with its lack of effect on sexual performance, have been explained to them In multiparæ in poor health or bad economic circumstances, sterilisation increases orgasm capacity in proportion as it reduces fear of conception

Studies of this type provide informative material on which to base our own views of the future of sterilisation Most English workers would feel that the legal denial of voluntary sterilisation to the individual is irrational, and that sterilisation of high grade defectives, based on persuasion, is eugenically desirable Compulsory powers will always, however, be rightly suspect in this country, especially when they are used, or may be used, to provide an easy administrative answer to a psychiatric problem Some of the American States have already provided experience from which we may be able to profit as time goes on

SERUM NEURITIS AND RELATED CONDITIONS

THIS year, apparently typical anterior poliomyelitis has been described in children inoculated within the previous 3–4 weeks with pertussis vaccine or with a mixture of this and diphtheria toxoid [1], and in the majority of these cases paralysis was maximal in the limb which had been inoculated A statistical study [2] confirms that during the 1949 epidemic this phenomenon was too common to be attributed to chance

Since Thaon's [3] report in 1910, atrophic palsy of one or both shoulder girdles has been recognised as a rare complication of the administration of serum [4] Serum neuritis has most commonly followed injection of tetanus antitoxin, but it has also been seen with diphtheria antitoxin and other sera The clinical course is fairly uniform, starting usually 5–10 days after administration of the serum At the onset there may be serum sickness and urticaria Severe pain is felt in the region of the scapula and upper part of the arm The pain lasts from a few hours up to a few days and is accompanied by atrophic paralysis of some of the shoulder-girdle muscles and at times slight sensory changes, usually on the outer side of the upper arm The distribution of the muscle involvement is usually radicular, the muscles supplied by C5 and C6 roots are commonly involved, but sometimes isolated muscles alone are paralysed, and the condition may be bilateral Winkelman [5] has recorded four similar cases with onset 7–14 days after smallpox vaccination Usually serum neuritis is ascribed to allergic œdema of the perineural tissues, but this explanation is unproved type were sufficiently alike for the data from them to be pooled. The exceptions were the two E N T wards which differed considerably—either in their practice or possibly in the type of patient admitted. One general surgical ward appeared to practise a high degree of early ambulation compared with the other wards of the same type. Leaving these exceptions on one side we were left with a sample of 522 patients drawn from twenty-one wards, distributed as follows: six general surgical wards (155 patients), six general medical wards (167 patients), four gynæcological wards (109 patients), six obstetrical wards (antenatal 41 patients, puerperal 50 patients). The estimates finally obtained, after adjustment, are set out in tables I–V.

Table I shows that under early ambulation the number of bedfast patients in the general surgical wards would be reduced to less than a third of the present value, and the number of fully ambulant patients would be increased by about two thirds. The data also suggest that the adoption of early ambulation would give an increase of about 10% over the current rate of throughput.

Table II shows that under early ambulation the number of bedfast patients in the general medical wards would be reduced to rather less than half the present figure, and the number of fully ambulant patients would be more than doubled. Here it seems that the adoption of early ambulation would give an increase of nearly 10% over the actual current rate of throughput.

In the gynæcological wards (table III) the number of bedfast patients would be reduced under early ambulation to little more than a third of the present figure and the number of fully ambulant patients would be nearly doubled. An increase of about 10% over the current rate of throughput could be expected.

TABLE III—GYNÆCOLOGY 109 PATIENTS

Category	I (%)	II (%)	III (%)
Actual regime	46·8	33·0	20·2
Early ambulation	16·2	45·5	38·4
Traditional	55·7	31·0	13·3

The materials for the estimate in table IV are less abundant and conclusions must be accepted with caution. It appears, however, that with early ambulation the number of bedfast patients would be reduced to less than half the present figure and the number of fully ambulant patients would be nearly trebled. The increase in throughput might be nearly 15%.

In interpreting table V caution is again needed. It can, however, be stated that with early ambulation the reduction in bedfast patients would be considerable—the table suggests a reduction of three-quarters—while the number of fully ambulant patients would be nearly doubled. The corresponding increase in throughput would apparently be about 20%.

Statistical Fluctuation

It will be appreciated that the percentages shown in all the above tables are average values. Where they are based on reasonably large totals—say, 100 or more—they are of adequate reliability. But it should not be overlooked that even if the above percentages had absolute accuracy as averages, there would be considerable day-to-day variation in an actual ward—this variation being larger with smaller wards. In a small ward one must therefore be prepared for much larger fluctuations in the numbers of patients falling into the three main categories than would be the case for large wards.

TABLE IV—OBSTETRICS (ANTENATAL) 41 PATIENTS

Category	I (%)	II (%)	III (%)
Actual régime	47·3	35·6	17·1
Early ambulation	22·2	27·8	50·0
Traditional	65·2	19·6	15·2

TABLE V—OBSTETRICS (PUERPERAL) 50 PATIENTS

Category	I (%)	II (%)	III (%)
Actual regime	48·0	27·0	25·0
Early ambulation	11·9	38·1	50·0
Traditional	60·4	24·5	15·1

For a given size of ward it is possible, from the above data, to make estimates of the degree of variation to be expected. This may have considerable influence on the selection of a satisfactory ward-size.

Increase of Throughput

For various types of ward we estimate from the available data what proportion of patients would have been discharged under early ambulation. Suppose in a given case this is 20%. Then only 80% of the actual patients in the ward would remain, and it can be shown that, if early ambulation reduces the length of stay of all types of patient in the same ratio, the relative change in throughput is given by 1 0·8 = 1·25 (i.e., an increase of 25%). In practice it is unlikely that all lengths-of-stay would be reduced in the same ratio, but without a detailed discussion of the distribution of length-of-stay and the differential effect of early ambulation on various types of patient it is impossible to say exactly what kind of modification is required. However, the simplifying assumption of *constant* reduction of length-of-stay adopted in this report is felt to give an important indication of the general order of improvement to be expected.

Discussion

During this survey of 836 patients in eight hospitals I had the opportunity of discussing early ambulation with the medical and nursing staffs, and as occasion arose with patients. Most of the doctors professed to believe in a modified form of early ambulation. In the same hospital there was often a considerable difference in the practice of ambulation in different wards. The opposition, such as it was, came mainly from gynæcologists. There was a sharp difference of opinion as to whether a pelvic-floor repair should spend 21 days in complete bed rest or whether she might get out of bed within 3–4 days of operation. One gynæcologist assured me that the last thing she would allow her patients to do soon after operation was to stand by the bedside and cough.

Obstetricians on the whole were keen to have their cases out of bed early but emphasised the patients' need of rest before going home to perform household duties. Surgeons appeared to prescribe early ambulation more than any other class of doctor. Emphasis was laid on the necessity for first-class technique. I was told that early ambulation was not suitable for the less proficient surgeons and that good anæsthesia must accompany good surgical technique. It was also pointed out that physiotherapy and exercises in bed can, in the opinion of some doctors, obviate the necessity for rising from bed in the first 24–48 hours. I was often told that if enough lavatories were provided close to the patients, far more of them would be allowed out of bed at an early stage.

Physicians on the whole tended to be more conservative. They had not the same enthusiasm for early length of stay of his hospital patients, and argues that the traditional physician or surgeon may not only keep his patients long in bed, but may also be compelled to keep them longer in hospital for repair of their wasted muscles and recovery from their general weakness. On the other hand, many doctors who get their patients up early are reluctant to discharge them until they have had a period of convalescence in hospital. This is particularly necessary in the case of obstetric patients, who on discharge tend at once to take up strenuous household duties.

If there were a full positive correlation between ambulation and discharge, the policy adopted would clearly not affect the proportion of ambulant patients in hospital but would affect only the capacity of the hospital in terms of patients treated in a given time. But there is not a full correlation between the two, as I shall show, and the effect of an early ambulation policy is therefore to increase the proportion of ambulant patients.

The Present Survey

STANDARDS

In the present investigation the technique adopted was to examine patients actually in a number of hospital wards and to assess their capacity to get up and look after themselves. In view of the controversy on the merits of early ambulation, it was decided that two assessments were necessary: (*a*) from the standpoint of a doctor practising early ambulation, and (*b*) from the standpoint of a doctor of the traditional school.

Patients were placed in three categories. These are more or less arbitrary, but each has direct planning implications and corresponds with a distinct phase in the cycle of recovery.

Category I.—The bedfast. (Patients who require intensive nursing and are unfit to get out of bed.)

Category II.—The partially ambulant. (Patients able to leave their beds to wash and use the water closet, who do not normally require a bedpan. Meals are brought to them in bed. The nursing attention which they require is not on the intensive scale of category I patients.)

Category III.—The fully ambulant. (Patients able to get out of bed, normally unaided and generally up for hours at a time. They still require nursing care but not as much as category II patients.)

In the first attempt to assess patients in this way the staff of the Bristol Royal Infirmary generously cooperated. The resident medical officer and the sister attached to each of 4 wards accompanied me round, and every patient was considered in turn by this panel of three. Full details of the clinical condition of the patient were obtained, and assessment was made in full knowledge of any complications or deviations from normal displayed by him. The *assessment* was made from the standpoints of the early ambulationist and of the traditionalist. In this first study no record was taken of the actual ambulation status of the patients; this was later recognised as a serious omission, and in later surveys a record was made of the actual stage of ambulation which patients had attained at the time of the visit. It also became apparent that a proportion of patients examined would already have been discharged under a régime of early ambulation. Their inclusion under category III thus tends to exaggerate the proportion of ambulant patients. It was therefore decided to include in future records a fourth category of "out."

In the main survey the original technique was followed and in all wards—except two in Edinburgh—I was accompanied by a doctor conversant with the condition of the patients and by the ward sister. In most cases the doctor was a senior registrar but in some hospitals more senior members of the *medical staff came* round with me. On the whole it appeared that the registrar had the merit of knowing the individual patients a also enough experience of his own specialty to app what alternatives in treatment and ambulation were feasible. He was at the same time less than the senior man to have developed firm victions one way or the other on the merits o ambulation.

After a little experience it was found not difficult to project one's mind into that of advoc the two schools of thought. The three catego ambulation were also fairly straightforward to id although it was at times not easy to place m cases.

TABLE I—GENERAL SURGERY 155 PATIENTS

Category	I Bedfast (%)	II Partially ambulant (%)	F am
Actual régime	50 3	20 0	
Early ambulation	16 4	35 0	
Traditional	66 7	17 3	

Some trouble was caused by the need to deci many patients would have been discharged u régime of early ambulation. While it was poss determine with some confidence the number of p who on "medical grounds" could have been discl it was clear that external considerations—such a conditions—would have made some such dis impossible. While allowance for external factors not in the circumstances be made for each ind patient, the reasons given for retaining in h some patients who could have been discharged the actual régime suggest that the crude figures b medical grounds alone would have to be hal practice.

Conversely, some allowance in the "tradit assessment is necessary. The discharge policy traditional régime would in nearly every case hav more cautious than that actually adopted, w result that a ward run on traditional lines woul contained patients—normally in category III—wh in practice, been discharged. If this fact were i the number of ambulant patients in a traditiona would be underestimated.

In the whole survey, twenty nine wards, acc *dating a* total of 836 patients, were examined

TABLE II—GENERAL MEDICINE 167 PATIENTS

Category	I (%)	II (%)	(
Actual régime	53 3	24 6	
Early ambulation	25 7	28 3	
Traditional	61 1	13 9	

were divided into clinical departments as fo eight general surgical wards (230 patients), eight medical wards (237 patients), six gynæcological (185 patients), five obstetrical (antenatal and pue 147 patients), and two ear, nose, and throat (37 patients). These wards were in eight hospit which five were teaching and three non teaching of the hospitals were in Scotland. All were of the general type with no special provision for long stay

RESULTS

The material collected in the early part of the s was later found to be incomplete, and was the rejected. In most cases the different wards of a type were sufficiently alike for the data from them to be pooled. The exceptions were the two E.N.T. wards, which differed considerably—either in their practice or possibly in the type of patient admitted. One general surgical ward appeared to practise a high degree of early ambulation compared with the other wards of the same type. Leaving these exceptions on one side we were left with a sample of 522 patients drawn from twenty-one wards, distributed as follows: six general surgical wards (155 patients), six general medical wards (167 patients), four gynæcological wards (109 patients), six obstetrical wards (antenatal 41 patients, puerperal 50 patients). The estimates finally obtained, after adjustment, are set out in tables I–V.

Table I shows that under early ambulation the number of bedfast patients in the general surgical wards would be reduced to less than a third of the present value, and the number of fully ambulant patients would be increased by about two thirds. The data also suggest that the adoption of early ambulation would give an increase of about 10% over the current rate of throughput.

Table II shows that under early ambulation the number of bedfast patients in the general medical wards would be reduced to rather less than half the present figure, and the number of fully ambulant patients would be more than doubled. Here it seems that the adoption of early ambulation would give an increase of nearly 10% over the actual current rate of throughput.

In the gynæcological wards (table III) the number of bedfast patients would be reduced under early ambulation to little more than a third of the present figure and the number of fully ambulant patients would be nearly doubled. An increase of about 10% over the current rate of throughput could be expected.

Conversely, some allowance in the " traditional " assessment is necessary The discharge policy of a traditional régime would in nearly every case have been more cautious than that actually adopted, with the result that a ward run on traditional lines would have contained patients—normally in category III—who had, in practice, been discharged If this fact were ignored, the number of ambulant patients in a traditional ward would be underestimated

In the whole survey, twenty nine wards, accommodating a total of 836 patients, were examined. These were divided into clinical departments as follows eight general surgical wards (230 patients) eight genera medical wards (237 patients), six gynæcological ward (185 patients), five obstetrical (antenatal and puerperal 147 patients), and two ear, nose, and throat ward (37 patients) These wards were in eight hospitals, o which five were teaching and three non teaching Tw of the hospitals were in Scotland All were of the acut general type with no special provision for long stay cases

TABLE II—GENERAL MEDICINE 167 PATIENTS

Category	I (%)	II (%)	III (%)
Actual régime	53 3	24 6	22 2
Early ambulation	25 7	28 3	46 1
Traditional	61 1	13 9	25 0

RESULTS

The material collected in the early part of the survey was later found to be incomplete, and was therefor rejected In most cases the different wards of a give

NEW YEAR HONOURS

THE list of honours published this week contains the names of the following members of the medical profession:

K.C.V.O.

DANIEL THOMAS DAVIES, C.V.O., M.D. Wales, F.R.C.P.
Physician to H.M. Household; physician to the Royal Free Hospital, London.

FRANCIS HUGO TEALE, C.V.O., M.D. Lond., F.R.C.P.
Formerly lecturer in bacteriology and immunotherapy, University College Hospital Medical School.

K.B.E.

PERCY SELWYN CLARKE, C.M.G., M.C., M.D. Lond., F.R.C.P.
Governor and commander-in-chief of the Seychelles.

K.B.E. (Honorary)

FRANCIS AKANU IBIAM, O.B.E., M.B. St. And.
Member of the executive council, Nigeria.

Knights Bachelor

KOFOWOROLA ADEKUNLE ABAYOMI, M.D. Edin.
Member of the executive council, Nigeria.

FRANK MACFARLANE BURNET, M.D. Melb., SC.D. Camb., PH.D. Lond., F.R.A.C.P., F.R.S.
Director of the Walter and Eliza Hall Institute; professor of experimental medicine, University of Melbourne.

WILLIAM KELSEY FRY, C.B.E., M.C., M.D.S. Durh., M.R.C.S., F.D.S. R.C.S.
Dean of the faculty of dental surgery, Royal College of Surgeons of England; consulting dental surgeon, Guy's Hospital, London.

GORDON MORGAN HOLMES, C.M.G., C.B.E., M.D., SC.D. Dubl., D.C.L. Durh., F.R.C.P., F.R.S.
Consulting physician, Charing Cross Hospital and National Hospital, Queen Square, London.

C.M.G.

CLIFFORD CRAIG, M.D., M.S. Melb., F.R.A.C.S.
Surgeon superintendent, Launceston General Hospital, Tasmania.

C.V.O.

GEORGE PROCTOR MIDDLETON, M.V.O., M.B. Aberd.
Surgeon apothecary to H.M. Household, Balmoral.

C.B. (Military)

Surgeon Rear-Admiral KENNETH ALEXANDER INGLEBY MACKENZIE, B.M. Oxfd, K.H.P.

Major-General THOMAS YOUNG, O.B.E., M.B. Glasg., K.H.P., late R.A.M.C.

C.B.E. (Military)

Air Commodore VYVIAN STEWART EWING, M.B. St. And., R.A.F.

C.B.E. (Civil)

JAMES BOYD, M.D. Belf., F.R.C.P.I.
Chief medical officer, ministry of health and local government, Northern Ireland.

Miss LUCY MEREDITH BRYCE, M.B. Melb., F.R.A.C.P.
Hon. director, blood transfusion service, Victoria.

JOSEPH STANLEY HOPWOOD, M.B. Lond.
Superintendent, Broadmoor Institution.

PETER JAMES KERLEY, M.D. N.U.I., F.R.C.P., F.F.R.
Director, radiological department, Westminster Hospital; adviser on mass radiography, Ministry of Health.

GEOFFREY MARSHALL, O.B.E., M.D. Lond., F.R.C.P.
Principal medical referee, Civil Service Commission; consulting physician to Guy's Hospital, London.

KAMIL MOHAMED ARIFF BIN KADIR MUSTAN, L.M.S.
For public services in the Federation of Malaya.

ADAM RANKINE, M.C., M.B. Glasg., lately Colonial Medical Service.
Director of Medical Services, Mauritius.

VINCENT BRIAN WIGGLESWORTH, M.D. Camb., F.R.S.
Director of the unit of insect physiology, Agricultural Research Council.

O.B.E. (Military)

Lieut.-Colonel JOHN ALISTAIR MANIFOLD, M.R.C.S., R.A.M.C.

Wing Commander HENRY LINDSAY ROXBURGH, M.B. Edin., R.A.F.

O.B.E. (Civil)

JAMES FANSTONE, M.D. Lond.
Surgeon and founder, Hospital Evangelico Goiano, Anápolis, Brazil.

THOMAS GILRAY, M.B.
Medical practitioner at Napier, New Zealand.

JOHN ALEXANDER JAMES, CH.M. Sydney, F.R.C.S., F.R.A.C.S.
Surgeon and physician, Australian Capital Territory.

ALEXANDER CAMERON MCKILLOP, M.B. Edin.
Senior assistant physician, New Zealand State Asylum Service.

WILLIAM HUGH CLIFFORD PATRICK, M.D. N.Z.
Regional medical officer, Ministry of Health.

MOHAMED ALI RANA, M.B.E., M.R.C.S.
For public services in Kenya.

ANDREW JAMES SHINNIE, M.D. Aberd.
M.O.H. for Westminster.

DON SAM DE SIMON, L.R.C.P.E.
Superintendent, Leprosy Hospital, Hendala, Ceylon.

SINNATAMBY SUBRAMANIAM, L.R.C.P.E.
For medical and social services in Ceylon.

ALLAN ROBERT STANLEY VICKERS, CH.M. Sydney.
For services to the Flying Doctor Service in Australia.

LEON JAMES WILLIAMS, M.D.
For public services in Bermuda.

M.B.E. (Military)

Major HAMILTON JAMES ELVERSON, B.M. Oxfd, R.A.M.C.

Surgeon Lieut.-Commander WILLIAM BOYD JACK, B.M. Oxfd, R.N.

Major TERENCE RICHARD JANSEN, L.R.C.P.E., Ceylon Medical Corps.

Surgeon Lieutenant TREVOR STANSFIELD LAW, M.B. Lpool, R.N.

M.B.E. (Civil)

ARTHUR GRIFFITHS FARR, M.B. Camb., Colonial Medical Service.
Acting senior medical officer, Tanganyika.

SAMUEL FERGUSON FLOYD, M.B. R.U.I.
General practitioner, co. Down.

Miss AGNES GRACE GILLESPIE, M.B. Lpool.
Missionary, Mary Calvert Holdsworth Memorial Hospital, Mysore.

JOHN JAMES SPARKS, M.D. McGill, F.A.C.P.
British vice-consul at Coatzacoalcos.

FRANCIS HENRY WHITEHEAD, M.R.C.S.
Chairman, Wandsworth and Battersea war pensions committee.

Bar to A.F.C.

Wing Commander HUGH PATRICK RUFFELL SMITH, A.F.C., M.B. Camb., R.A.F.

A.F.C.

Squadron Leader JOHN STAFFORD HOWITT, M.R.C.S., R.A.F.

Personal Papers

PATIENT'S PROGRESS

WHAT are the functions of an almoner? I had been working as one for two weeks and I still wasn't sure, when one day in April, 1947, Peggy hobbled into my office on two sticks. Lank grey hair framed her colourless face. Her eyes peered owlishly from behind large round spectacles. She seemed highly nervous, rather dull, and rather deaf. She had very little to say for herself and she seemed very much under the influence of Mrs. Bullock,* who accompanied her. Mrs. Bullock was a large, well-dressed, loud-voiced, overpowering woman, who, when asked if she was a relative or friend, announced that she was "one of the Good Samaritans of this world." So the Good Samaritan, protesting loudly, was asked to wait outside while I tried to sort out the difficulties that might arise when Peggy came into hospital for the cup arthroplasty to her hip. This is generally a two-year job, and at that time meant three months in hospital, several weeks wearing a walking iron, a long convalescence, and then a possible work readjustment. This programme often creates financial and domestic problems, and I wanted to talk to Peggy about her particular difficulties undisturbed. The interview was a complete failure. Peggy was too afraid to speak, and to my chagrin I had to ask the Good Samaritan to come back. She held forth at length about her own virtues, and implied that Peggy lived with her as a friend, for whom she was ambulation, and, perhaps because there is no starting point for treatment corresponding with an operation, the tendency was towards rest in bed while there was any doubt There were exceptions, thus, in the medical wards in two hospitals about half the patients were "up" in spite of the fact that the average ward age at the time of observation was less than for medical wards elsewhere In another hospital the practice of early ambulation and short stay appears to have been partly attributable to there being many consultants, each with only a few beds which he naturally tried to put to the fullest use In addition there were facilities for transfer of convalescent cases to other hospitals

---

* Names throughout this article are fictitious.

The practice of early ambulation at first imposes a heavy strain on nurses, but later it eases the burden I have seen two nurses straining to keep a cholecystectomy patient upright on the edge of her bed She was of the 'fair, fat, fertile, and forty" type, weighing possibly 16 st, and as she swayed from side to side looking miserable it was all that they could do to prevent her from falling on the floor The initial effort to get a postoperative patient up is not always easy

Once early ambulation is established, the patient can take the responsibility for his intimate hygiene and so relieve the nurses of some of their work On the basis of the figures obtained in this survey, if we compare the number of patients actually bedfast with the number who would be bedfast under the practice of an early ambulationist, we find that on average about two thirds of those patients at present using bedpans in surgical wards would be liberated From my discussions, I am convinced that surgeons would welcome this, and very little objection from patients may be anticipated

Closely related to the problem of bedpans is the problem of bathing In the hospitals which I visited it was usual to find one bath for 20 patients or perhaps two for 30 I was assured in one hospital that every ambulant patient was expected to have a bath, which would be entered in the "bath book" As baths were only permitted on the ninth day in this maternity ward, the number of potential bathers was not very large In another ward even colostomy patients bathed themselves and the number of baths provided was considered inadequate It seems clear that at present there are not enough baths to meet the needs of patients, and that if early ambulation were to be practised more, the bathing facilities would have to be increased accordingly Perhaps because of the very inadequacy of bathing facilities in most existing wards the matter is given up as a bad job During this survey, in frequent visits to wards at all times I have never found an occupied bathroom

Summary and Conclusions

For more than fifty years early ambulation has been intermittently advocated by members of the medical profession During the war years expediency forced many doctors to adopt it in varying forms Around 1944 many papers on the merits of early ambulation were published in America, and in 1946 the appearance of Leithauser's book stimulated others to follow his example, though often they modified his technique

In the present survey 836 patients in eight acute general hospitals were assessed, mostly under three heads (*a*) their actual stage of treatment and ambulation, (*b*) the stage of treatment and ambulation which they would have reached under the care of a doctor practising early ambulation, (*c*) the stage of treatment and ambulation which they would have reached under the care of a doctor of the traditional school

In the wards studied, great variations were noted in the length of rest prescribed, and in the precipitancy with which patients were raised from their beds after operation, childbirth, or illness The practice of early ambulation in modified form was commonly observed. Reliance is often placed in physiotherapy and bed exercises, as a substitute for the early rising advocated by Leithauser

It was clear that many more patients would be permitted to "rise early" if the necessary facilities were provided Those partially ambulant would require more lavatories and bathrooms, and a full régime of early ambulation would call for increased sitting up space and dining facilities Moreover, early ambulation throws an initial strain on the nursing staff and for this reason some of the patients observed in the hospitals were not up as soon as the surgeon wished

From the results of this survey the following tentative conclusions are reached

1 A very strong case can be made for the practice of early ambulation, provided the necessary surgical and technical skill can be attained

2 In the great majority of wards studied, the normal practice still approximates much more closely to a traditional than to an early ambulation régime. Although the ambulation policy has affected surgical and gynæcological wards more than medical wards, the former still appear to offer a greater relative scope for its extension

3 It can be inferred from the figures that, if the practice of early ambulation prevailed, 70–90% of patients in the types of wards covered would require the use of basins and water-closets, and 40–55% would require day space These percentages may be contrasted with the present 45–55% requiring the former and 15–30% requiring the latter facilities It should be emphasised, however, that very few hospitals are equipped to provide for even these current percentages

4 An important secondary consequence of early ambulation is the increased effective capacity of the hospital resulting from reduction in the length of-stay necessary The data suggest an increase in the rate of throughput varying from about 10% in medical and gynæcological wards to 20% in obstetrical (puerperal) wards

I am very grateful to the late director of research, Mr John Madge M A, A.R I.B A, for assistance and advice Other team members, particularly Mr Norman T J Bailey, statistician to the department of human ecology, Cambridge University, and Dr Barbara Duncum, D PHIL. also gave me valuable help which I wish to acknowledge Permission for publication of this article has been granted by the Committee controlling the investigation

Miss Meekins had been ill and had had an operation, and they had sent her to a convalescent home When she left she went to stay at a hostel and then, suddenly, all who knew her lost track of her

* * *

Six months later she walked into my office looking very smart and rather condescendingly told me that she had at long last contacted her long lost father, who was a retired estate agent in Philadelphia, and he was coming over to fetch her back to live with him I found that she was working as a housekeeper in Pimlico, having found the job herself She brought her father to see me when he arrived—a dapper little man in a panama hat I must confess I had wondered if there was anything phoney about this move, but the family likeness was too strong for there to be any doubt about his identity

So Miss Margaret Meekins, of independent means, sailed to the U S A, first class, on Aug 17, 1950

The Wider World

FIJI REVISITED

Sir Philip Manson-Bahr
C M G, D S O, M D Camb, F R C P
CONSULTING PHYSICIAN TO THE HOSPITAL FOR TROPICAL DISEASES, LONDON

I HAVE recently revisited the Fiji Islands after a lapse of forty years Naturally, there have been great changes A good road now encircles the main island of Viti Levu, large numbers of cars are to be seen in Suva, the capital, and everywhere the standard of living is high The Indians, who in 1910 were sugar plantation labourers, are now landowners on a considerable scale, and a great deal of the trade of the islands is in their hands Under a paternal government they enjoy full privileges, including free schooling and hospital treatment The Fijians, who in 1911 were a race only recently come under British rule, are now a civilised, highly organised community in whose ranks doctors, native medical practitioners, dentists, administrators, teachers, and all manner of technicians are to be found

Their very diseases have also changed Bacillary dysentery, which in 1910 I went out to investigate and which was then rampant, has practically disappeared I found at that time that Shiga's bacillus was spread mainly by the ubiquitous house flies,[1] but now, probably owing to better sanitation and the application of D D T, the number of flies has greatly decreased and so has the incidence of bacillary dysentery Since 1943 a Mosquito Control Service, which was originally organised and directed by a remarkable layman, the late D W Amos, has been in operation in the islands The Fijians employed in this service acquire a specialised knowledge which enables them not only to recognise various species of mosquito but also to distinguish their larval characteristics So efficient has been their work that in the main island of Viti Levu filariasis has largely disappeared

In 1910 I was able to demonstrate[2] the transmission of the filaria of the Pacific, *Wuchereria bancrofti* var *pacifica*, by a new species of mosquito, now known as *Aëdes scutellaris* var *pseudoscutellaris* Theob—an insect which has peculiar breeding habits frequenting mostly small pools of water, discarded tins crab holes and coconut shells By eliminating these reservoirs the numbers of these mosquitoes in the vicinity of houses have been much reduced It has also been found that cutting the grass and clearing the bush around the native houses, or *buris*, interrupts the parasitic cycle by eliminating resting places of this mosquito after it has been engorged with human blood

In recent years a number of subvarieties of this main species have been separated in various islands of the Pacific, one of which—*A scutellaris* var *horrescens* Edw,[3] a forest-frequenting form—has been recognised This variety breeds mostly in collections of water in the axils and branches of forest trees and in tree holes, whereas the first named is associated with cultivated areas and human habitations The larvæ of these two varieties are quite distinct, those of *horrescens* being covered with hairs and thereby easily recognised, though the adult females are identical

It appears probable, from what I was able to accomplish, that *horrescens* is incapable of transmitting the human filaria This is important, because any systematic measures against this forest loving species would be impossible to carry out Here then, is a pretty problem to be solved—namely, what is the substance or agency which endows a particular variety of mosquito with the property of transmitting the filaria worm ?

Unfortunately, there is much pulmonary tuberculosis among the Fijians, as has been made evident by mass radiography Tuberculosis, filariasis, yaws, typhoid, and paratyphoid are the chief scourges of these people, and probably any sanitary measures taken against one of them would have some effect against the others The rebuilding of native houses on modern lines and the provision of a good water supply and general sanitation are now being vigorously undertaken

Kwashiorkor, or malignant malnutrition, has lately been discovered in undernourished and neglected children in the back areas of the main island It is odd that these isolated cases have come to light when the general nutrition of the natives stands at a high level Undulant fever of the abortus type has also recently been discovered, and much more work requires to be done on fevers of short duration hitherto lumped together under the diagnosis of dengue

Many channels for research remain unexplored so far, for want of specially qualified doctors For instance, the bacteriological collection contains over 100 strains of the salmonella group waiting to be classified, and there are interesting possibilities for hæmatological research in a peculiar form of megalocytic anæmia which is prevalent among the island born Indian population and which appears to have a seasonal incidence In the wards of the Colonial War Memorial Hospital in Suva, medical practice is concerned with a medley of cases such as were seen in this country over a century ago Since systematic necropsies have been conducted, many hitherto unsuspected diseases, such as rheumatic carditis, have come to light

Dr J M Cruikshank, the principal medical officer, is a far seeing administrator who gives great encouragement to any of his officers who show an inclination for study outside the usual routine The Central Laboratory in Suva is a most efficient institution, and the technical ability of the Fijian and Indian assistants, under the able direction of Mr J E Pery Johnson, has to be seen to be believed

By some, Colonial officials are regarded as swathed with red tape, but as far as Fiji is concerned nothing could be further from the truth I know well that anyone with qualifications to undertake medical research work would be welcomed and would be given every assistance For those with the pioneering spirit and keen and inquiring minds the opportunities are great

The chance is not given to everyone to recommence a piece of work on which he was engaged so long ago, and I am grateful for being allowed to go to Fiji and once more work under my own steam so to speak During my four months stay many courtesies and privileges were afforded me by the Governor, Sir Brian Freeston, and by the Fiji government and its officers They gave me not only laboratory accommodation but every facility I needed for my research Everyone I might say, whether within the government or without joined in helping me accepting responsibility She avoided the question of whether the patient was an employee Peggy she said, had done a little work for her, but was not working for her now

[3] Edwards F N *Bull ent Res* 1935 26 2

I was far from happy about the pair They didn't fit together, and the patient was so dreadfully nervous But the queue outside the door was long, and I knew I should have time to get to know Peggy when she came into the ward

Nearly two months later she came into the orthopædic ward and I saw her next day She still seemed too nervous to talk, but said she liked working for Mrs Bullock and would not change for anything in the world Her operation was postponed a week, which gave me a chance to make friends with her Finally she broke down and admitted she did not want ever to go back to Mrs Bullock

* * *

She could not remember her mother, but until she was 10 she lived with her father, two brothers, and a sister in Manchester When she was 10 her father went to America and she and her two brothers went to live at an orphanage When she was 16 she left and went to work for Mrs Bullock, whose household consisted of eight people Although her relatives tried to get in touch with her they were discouraged, and she was not allowed to see them or communicate with them

She was now 44 and for the last 30 years she had worked very hard Her hours were long and she had no life to call her own She had scarcely any time off When she did occasionally go to the cinema, her times of going out and coming in were strictly supervised She was paid 10*s* a week During the war her mistress was not allowed to keep two maids There was apparently another wretched downtrodden maid, so Peggy had to go out to work She was employed by two or three local women to do domestic work for a few hours a day, but she still had to work for Mrs Bullock before she went out and after she came in At one point she revolted and ran away to one of her other employers, but Mrs Bullock followed her and threatened the other employer to such an extent that Peggy returned For her outside work she was paid 30*s*, but Mrs Bullock deducted £1 and left her 10*s* out of which she had to pay her N H I, leaving about 7*s* for all her needs After all these years she had £10 in the bank and a few Savings Certificates While she was waiting to come in for her operation she was sent to spring clean the country cottage, and the day before her admission she washed blankets.

* * *

This story seemed fantastic, but I contacted one of the women for whom Peggy had worked, and she confirmed it She too seemed a little frightened of Mrs Bullock, who had told her she was not to visit Peggy in hospital as anyone except Mrs Bullock upset the patient! Peggy's panel doctor, who had sent her to the hospital, said he believed my suspicions to be correct He had had to make special arrangements to see the patient when she was supposed to be out at work

The first thing to be done was to get Peggy to pluck up enough courage to decide not to go back to Mrs Bullock This was no easy task, as every time I got her to the point Mrs Bullock would visit her and play on her emotions to such an extent that she would weaken again Matters were finally brought to a head when I wrote to Mrs Bullock, asking her to see me to discuss certain difficulties and at the same time to let Peggy have her savings book, clothing coupons, &c Evidently realising that something was afoot, she did not reply Eventually, having laid in wait on visiting days for several weeks, I managed to meet her in the ward There was an unhappy scene, which was impossible to avoid, and Mrs. Bullock left threatening me with legal action for attempting to coerce Peggy to leave her However, she apparently thought this over and decided to throw in her hand She sent Peggy her belongings, which were not worth having, and we never heard of her again

Now that Peggy had had her pillar of strength removed she became very dependent on me, and my next big task was to give her a sense of independence I started by successfully tracing some of her family, and for weeks I would find odd people turning up at my office saying they were relations The effect on Peggy wa amazing and her delight was touching to see She bega to have faith, realised that she was not entirely friendles and started to build up hope for the future

She had only done domestic work and she had not th mental ability for anything more complicated It wa thought that she would be fit to go on with this kind work eventually, so we promised to help to find her suitable residential post when she was fit She the decided she would like to work for the hospital—a sta which quite a lot of patients go through I did not thin it was a very good idea, for I was afraid she might rema too dependent on me, but I did not at that time want t rob her of her sense of security and thought she woul have plenty of time to change her mind An intervie was arranged with the domestic supervisor, who said sh would be able to find Peggy a suitable job when the tim came

By the end of September, 1948, Peggy could just wal with a walking iron At the beginning of October took her to a convalescent home where she could hav physiotherapy, and she stayed there several weeks. O her return she spent a weekend with one of her relative in London and came to the outpatient clinic for a check up Then she went to stay with relatives in Mancheste until after Christmas, when it was thought she would b ready to start work During her stay in Mancheste physiotherapy was arranged for her locally at a reduce fee, which the relatives were able to pay

* * *

It was a changed Miss Meekins who came to see m at the clinic at the end of January I hardly recognise the self assured vision with sparkling eyes She looke at least 20 years younger, her face generously made u and hair waved There was also a coy air about he which I found puzzling until in a rush of confidence sh confessed that she was now a betrothed woman abou to become a bride in March So that accounted for th strange letter I had received that morning asking me t give some unknown person a reference on her with a vie to a proposed engagement In my ignorance I ha interpreted the letter to mean that she had found a jo and that she would not need the post that was about t be offered to her at our Seaview convalescent home There are moments when it is difficult to contain one' curiosity, and by devious means I discovered that sh had met her fiancé by answering an advertisement in th *Evening News* He was a steady church going ma widower, and male nurse, at present out of work, bu approved by her relatives

I advised her to take the job at Seaview for the tim being, which she did Gradually she began to leave o her walking iron and have less treatment Although a first her letters were frequent and demanding, thes gradually lessened. The engagement fell through, an we had to deal with a broken heart, but it healed fairl quickly and I did not hear from her for long interval At one point there were suspicions that she was guilt of petty thefts, but she got over this too Two yea after I first met her I decided that she was thoroughl rehabilitated, for the only news I had was that she wa getting around well and I ought to see her running dow the drive to meet her latest boy friend I believe sh became engaged to a bus driver at Seaview at this tim

In October, 1949, Miss Meekins turned up again, havin got herself a job at a hospital as doctors' maid at a bette salary She was beginning to feel rather tucked away i such an out of the way place as Seaview Three month later, the almoner of that hospital rang to say tha

Letters to the Editor

CORONARY DISEASE AND MODERN STRESS

SIR,—Recovering from an acute respiratory infection has given me more leisure than usual to peruse your issue of Dec 23, and with it Dr Stewart's article This I much enjoyed, though more as an English essay than as a scientific paper I suppose one can enjoy an essay and still question some of the premisses and disagree with some of the conclusions of the essayist

Dr Stewart starts with a few dogmatic statements which are surely very controversial and goes on to a cautious and fairly critical examination of the evidence as to whether "modern stress" *has* caused an increase in coronary disease and finds that much of this evidence is inconclusive or conflicting He does, however seem convinced that "the better educated and those who work with their brains are more liable than their fellows to coronary disease" The only statistical evidence for this which Dr Stewart cites (and it is surely a question of statistics) is (1) Dublin et al,[1] that the mortality ratio of heart disease amongst doctors is 1 18 of the general male population of parallel age—not a very striking figure compared with influenza, for instance (*vide infra*)—and (2) the Registrar General s Decennial Supplement for 1931 (the last to be published) which shows that if the death rate from coronary disease in the general male population is 100, it is for

Agricultural workers	32
Coalminers below ground	40
Banking and insurance officials	183
Anglican clergy	218
Physicians and surgeons	368

Now I am very fond of the R G's Decennial Supplement and happen to have it in bed with me, but its accuracy depends, as I have pointed out before[2] upon the accuracy of the material from which it is compiled —namely death certificates The majority of persons do not die in modern well equipped hospitals, do not have post-mortem examinations, and are not seen by consulting physicians or cardiologists The death certificates from which these figures were compiled were from the years 1930–32 Levine's classical article on coronary thrombosis was published in 1929, and although the condition had been recognised before, and the association between coronary artery disease and angina pectoris had long been known, it is fair to say that coronary thrombosis as a cause of death was not commonly diagnosed even by experienced physicians until about 1930, amazing though it may seem The majority of such deaths would be certified as myocarditis and myocardial degeneration Diagram 3 (p 30) of the Decennial Supplement shows clearly that while "angina pectoris' increases as we go up the social scale myocardial disease does exactly the opposite, and the table on p 162 shows that the figures for myocardial disease ' are for banking officials, &c., 59, and for anglican clergy 57, whereas for cotton strippers and grinders (social class IV—surely not educated brain-workers) the figure is 213 Doctors show an excess in both categories

As the R G (or one of his henchmen) points out on p 60

> degenerative disease in the heart affects all classes of males to much the same extent but whereas amongst men whose social conditions are most favourable it tends to express itself as angina pectoris or coronary disease, at the other end of the scale it tends to take forms described on death certificates as myocarditis or myocardial or cardiovascular degeneration.'

This is surely a most important statement, without which most of the figures quoted by Dr Stewart are very nearly meaningless (He probably had not the benefit of a respiratory infection when compiling his paper)

I venture to suggest that the likelihood of persons dying in 1930–32 having seen a consulting physician or cardiologist might well be in the following order

Physicians and surgeons
Anglican clergy
Banking and insurance officials
Coalminers below ground
Agricultural workers

and that the chief difference is not one of disease but of nomenclature Perhaps the 1950–52 figures will show an equally nice social distinction between ' coronary thrombosis" and "myocardial infarction"

Despite this there is still a slight preponderance of deaths due to heart disease in males of social class I, and probably a considerable preponderance in doctors I am not trying to make out that it does not exist—merely that a great deal of it is illusory

Incidentally, if my present illness should require entry on a death certificate I feel sure that it will be described (probably erroneously) as "influenza," and I am sorry to note (Decennial Supplement, p 256) that the standardised mortality ratio for doctors of my age group is 133 (or 1 33 in the terminology of Dublin et al.), but the fact that the highest rate for influenza is amongst "makers of non metalliferous mine and quarry products" restores some of my hopes for the New Year As a bedside author I can recommend the R-G very highly

USE OF BACTERIA TO CONTROL VIRUS DISEASES

SIR,—Two articles on bacteriophage in no 14 of *Science News*, by the late Prof F W Twort, F.R.S, and by the late Prof Felix d'Herelle, gave me what seems to be a novel idea for controlling virus diseases So little success has so far been achieved in this field that practical bacteriologists and pathologists might think the idea worth pursuing

Professor Twort writes (p 14)

> 'In test tube experiments it is easy to arrange conditions so that a bacteriophage will kill off its host the bacterium but it is equally easy to arrange another set of conditions in which the bacterium will kill or inhibit its invading bacteriophage '

Since there seems to be good evidence that some bacteriophages cure certain bacterial diseases, and that bacteriophages are viruses, one naturally asks whether the opposite process can occur Can virus diseases be controlled by suitable bacteria ? Dialectically this seems to demand the answer Yes If some viruses exist at the expense of bacteria, it is surely probable that some bacteria normally exist at the expense of viruses

Where can one find such bacteria ? Dr d'Herelle (p 47) points out that the bacteriophage that deals with dysentery and other intestinal infections may be found in the stools of convalescent patients This suggests that the search for suitable bacteria to counter a virus disease should begin in patients convalescent from that disease or perhaps in contacts who did not develop the disease d'Herelle is convinced that, in some bacterial infections, the patient's spontaneous recovery invariably coincides with the appearance of bacteriophage in the patient and is in fact attributable to the presence and activity of the bacteriophage. This raises the question whether recovery from virus infections is not dependent, in some cases at least, on the appearance of specific bacteria which attack the virus This may be the function of some of the benign bacteria harboured by the normal healthy body

In England Now

A Running Commentary by Peripatetic Correspondents

THEY do things in style north of the border On a recent visit to a Scottish university my fellow traveller and I (we wore blue, not red, ties) were invited, unexpectedly and in spite of our state of undress, to attend the biannual dinner of the Medical Faculty An impressive gathering of the professoriate, including at least two knights, bade us welcome, and dinner jackets were accompanied by boiled shirts and fly-away collars —none of your modern soft fronts and turn-me downs After the aperitifs we sat down to a traditional Scotch dinner, with the Dean, the essence of bonhomie, seated in his high chair in the centre First there was Scotch broth, with carrots intult and neeps intult and all the other "intults" that so intrigued Queen Victoria Then strange noises were heard from the kitchen, and presently a piper in full dress regalia swung into the dining hall, followed by the chef holding aloft a sonsy haggis, that chieftain of the puddin' race After the dish had been piped round the table and the chairman had stabbed it fiercely with a dirk, the piper was rewarded with his glass of whisky—it was a large whisky and he a young student, so he may be forgiven for not draining the glass at a gulp—and the company proceeded to wash down this tasty morsel with the same Highland dew With turkey and cranberry sauce we drank a fine claret, that Scottish symbol of the Auld Alliance Then came the plum pudding, followed by mince pies and then a mushroom savoury After the toast of the King, the vintage port was circulated (clockwise, of course), and its mellowing influence brought forth a succession of pawky stories, capped by one from the Dean about an Aberdeen plumber who, weary of life, decided to end it all, they found him in the kitchen with one end of a gas-pipe in his mouth and the other end fixed to the company's side of the gas-meter And so into the cold wintry night But one felt that in Scotland at any rate a professor still has some standing—and an appreciation of the good things of life

* * *

Among the more entertaining of our uninvited, though none the less welcome, guests at the clubhouse when we held our Christmas party was the resident engineer Dressed unobtrusively in a sports coat and grey bags he oozed inconspicuously into the bar at 8 30 P M and stayed there In my capacity as host I didn't really get around to him till about 12 50 A M., by which time he was feeling fine He began by offering me two or three pounds to pay for some of the whisky he had drunk. I liked the "some" "Don t like spending all time in bar," he explained, "rather dance but can t, knee trouble" I expressed sympathy "You're doctor," he went on, "understand these things, football," "Dangerous game," I agreed, "I gave it up when I was thirty-five" "Not just joint,' said the resident engineer, "it's carlidge, see? Semi semiloolar carlidge You're doctor Understand" I assured him I did and moved on Ten minutes later, with a young woman holding him up, he was steering an erratic course round the dance floor, semiloolar or no semiloolar In a dual sense he was out on his feet

* * *

My disability is cold feet—not the moral kind but the physical My feet used to get so cold on most winter evenings that it often took half an hour or more to get to sleep I tried and rejected (1) a hot-water bottle, which warms only the soles of one s feet, (2) bedsocks, which are a bit better but make the feet unbearably hot later in the night, (3) violent exercise shortly before bedtime, which is only partly effective and a nuisance to oneself and others, (4) warming the feet before a fire, which also deals only with one's soles and is of little use unless prolonged for about 20 minutes, and (5) soaking the feet in hot water, which is effective but laborious and time consuming A further objection to the last three methods is that they are difficult to practise away from home

The only treatment I have found at once simpl and effective is as follows (*a*) on arrival home in the evening, change into a dry pair of thick woollen socks. (*b*) Bedroom slippers need not be worn, but sit all evening with the feet on a cushion or hassock (*c*) Last thing before getting into bed, wrap a big woollen scarf tightly once round one foot and then round and round both feet together, and tuck in the end Within 2 minutes the f are perfectly warm and one should be fast asleep (*a*) and (*b*) are impracticable I can get to sleep in 5 minut on (*c*) alone, however cold my feet, and they do not too hot later, because the scarf slips off during the nig

Warning Be careful not to leave the scarf in b when away from home, it may be difficult to expla to your hostess why you declined a hot bottle

* * *

At this time of year I have to decide which of the not and entries in my 1950 pocket-diary deserve transplantin to the 1951 presentation model Addresses and telepho numbers are usually copied in year after year, but th time I shall use pencil for my Registrar friends and f my young sister who is training at a London teachin hospital and requires the Society column of the *Tim* to record her frequent transitions from the Londo nurses' home to the country branch and vice versa.

It is always amazing, on thumbing over the leaves, t come across entries which I have no recollection of makin Some at once recall a theatre date or a dinner wit Smith, but others are more obscure That name an address I came across in the July pages needed severa minutes' concentrated thought before it revived th memory of the charming Americans I met in the Tyrol promised to write to, and have till this moment shamefully forgotten Others are still more baffling—a complicated list of groceries eventually reveals itself as a recip for Christmas pudding copied down for my mother from a patient's dictation, and "Phone Rodgers" on Sept 1 must have had some urgency at the time though now I can remember no Rodgers in my life I hope remembered to phone him, anyhow

One year I found an old entry of "Constance White,' and the effort to recall this mystery woman cost m many sleepless hours before a friend, showing me round his garden in the summer, asked casually if I had bought a rosebush of that name—he had seen me take the name down in my diary the year before

* * *

Opening the Christmas mail is not without its profes sional hazards It was bad enough this year to open a 2½*d.*-stamped envelope and find it contained only a circular disguised as a Christmas card from Messrs Drug and Bottle, but my sister, a laywoman, who was helping me sort the mail uttered a shrill yelp when she opened one envelope and, instead of robins and holly, found a realistic coloured illustration of a gastric ulcer in the early stages of healing "This is rather a nice one, don't you think?" I asked nonchalantly, a few minutes later, putting between her still tremulous fingers a cheery folder emblazoned with the motto "In cases of hæmorrhoids   " and illustrated, again in colour, with a fine proctoscopic view "They must think you're a psycho analyst, dear," was her retort

* * *

In a Northern European capital, British anæsthesia was demonstrating its best to an assorted group drawn from every quarter of the Continent One drug after another had been injected into the vein, cunningly found in a difficult arm the endotracheal tube had been slipped into place with a facility that made the onlookers goggle, and the tubes and etceteras all fixed in place The patient lay corpse like and ready, and silence reigned except for the creaking of the breathing bag being nonchalantly squeezed The opening into the peritoneum appeared like a yawning crater, at the bottom of which could dimly be discerned some coils of gut Suddenly there was a clatter as the Professor threw down his instruments He glared at the top end 'I cannot work like this There is too much relaxation," he said, "too much relaxation"

In this country 20,000 people die every year from ulmonary tuberculosis, most have advanced disease hen the diagnosis is made All money spent on tempts to save these people has been wasted If uch takes one year to die in hospital then 20,000 in ospital for one year at £300 a year each = £6,000,000 (This is the cost of running 1000 units, or twenty times he cost of the present mass radiography service)

What good are new quarters for the reception of those lready doomed by late diagnosis ? What good are more eds for the dying with more staff to attend their exitus ? Money spent on early diagnosis is money well spent

REGISTRARS

SIR,—In view of the new regulations regarding egistrars, may I suggest that, out of fairness to applicants, every advertisement for a registrar appointment should clearly set out certain extracts of the conditions and terms of service

These extracts should explain that a registrar will be liable to dismissal after his first year of appointment, and that in any case his appointment will terminate after his second year He will be entitled to apply for a senior registrar post if he is permitted to proceed to this stage

It should be stated that if his application is successful and he obtains the position of senior registrar, he may be entitled to serve in this capacity for three years or in certain circumstances four years, and that his appointment as a senior registrar will then be terminated.

I feel, from personal experience of registrars, that future applicants may not be aware of the full nature of their contracts Attention should be drawn to the recurrent reviews and possibility of dismissal, and the ultimate termination of appointment

EFFECTS OF CORTISONE ON EARLY FIBROSIS OF THE LIVER IN RATS

SIR,—Dr Aterman's article of Nov 11 prompts us to record our results in similar experiments

Thirty male rats were treated in a glass topped chamber for 4 minutes daily with carbon tetrachloride inhalations One group of rats was used as controls and another group was injected subcutaneously with Cortisone (Ciba) 1 mg daily The animals were killed 20 and 45 days after the start of the experiment

Post-mortem examination of cortisone treated rats showed thymolymphatic and adrenal atrophy the splenic and hepatic hypertrophy, following the treatment with carbon tetrachloride was less severe in the rats treated with cortisone than in controls

Histological examination of the liver in the controls showed severe fatty degeneration as well as marked perilobular and intralobular reticulosis and fibrosis with consequent structural alteration of the lobules The growing reticular and collagenous tissue was found to be rich in acid mucopolysaccharides (Hotchkiss method) and alkaline phosphatase (Gomori method) Numerous mitotic, and sometimes atypical figures were present in the hepatic cells cells with giant nuclei were assembled in regeneration islets

The fatty degeneration in the livers of the cortisone-treated animals was practically of the same extent as in controls Glycogen was definitely increased A moderate increase of reticulum was observed in the portal spaces but collagen tissue was absent or very scanty The fundamental structure of the hepatic lobule was mostly preserved the new connective tissue was very poor in acid mucopolysaccharides, and practically no alkaline phosphatase was present The hepatic cells showed very few mitotic figures they were not assembled in regeneration islets nor did they contain giant nuclei

We may conclude that cortisone definitely modifies the evolution of carbon tetrachloride cirrhosis Fatty degeneration is not affected, but fibrosis, reticulosis, and parenchymal regeneration are greatly inhibited, such an effect is probably produced through a primary action on mesenchymal tissue and inhibition of cellular proliferation

ADJUVANTS TO STREPTOMYCIN

SIR,—The thorough and ingenious experimental studies upon which Dr Cathie and Dr MacFarlane based their use of streptokinase in the treatment of tuberculous meningitis gave good grounds for hope that this substance would be of value in the treatment of the disease, and their report (Dec 16) on a series of cases treated with it is of great interest

It is disappointing to note that when their cases are taken as a whole, including the relatively unsuccessful preliminary cases (as with the other quoted series in their table), the proportion of survivors is only 47% although two thirds of their patients were treated with streptokinase This is not very different from the results of others, and compares with 46% survivors in the group treated without streptokinase and reported by Dr Russell and myself[1] The cases that we reported are described by Cathie and MacFarlane as "selected" We would point out that the reason they were not successive admissions to the hospital was that in an undergraduate teaching hospital it is possible to set aside only a limited number of beds for this disease and many children admitted with tuberculous meningitis had to be sent elsewhere for treatment The selection was not made on clinical grounds but on the availability of a bed when each new case was admitted

The results obtained by Cathie and MacFarlane suggest that streptokinase may have some effect in reducing the incidence of serious sequelæ in patients who recover from tuberculous meningitis, but their evidence so far does not seem to indicate that it is capable significantly of increasing the proportion of survivors.

Royal Hospital for Sick Children
Glasgow
PATRICK MACARTHUR.

SIR—Dr Cathie and Dr MacFarlane have very ably described the methods of treating cases of tuberculous meningitis developing hydrocephalus and spinal block. We agree that ventricular drainage and administration by this route is necessary in the presence of raised intracranial pressure and hydrocephalus.

Changes in the flow of cerebrospinal fluid (C.S.F.) and even complete block may, however, be due to obstruction in the spinal canal rather than at the base of the brain Dr Cathie and Dr MacFarlane described such a case (no 37), which was admitted with a block in the dorsal region Surely it should be unnecessary to tap the ventricles in these cases if cisternal puncture is satisfactory ?

At present we have a patient, very similar to their case no 37, in which there was complete block of the spinal canal.

In this case tuberculous meningitis had been very satisfactorily treated with streptomycin given by repeated cisternal punctures The patient was given 100 mg of streptomycin in 5 ml of normal saline by cisternal puncture on alternate days for over three months Each injection was immediately followed by some vomiting but there were no other reactions This child previously had burr holes made in his skull The ventricles were not dilated and were tapped with difficulty each ventricular tap was followed by temporary but marked mental disturbance, and the taps were therefore abandoned after one week We now consider that ventricular puncture was unnecessary and probably harmful in this case polymorphonuclears, 19% lymphocytes 33% monocytes, 4% eosinophils, and 4% band cells Blood culture was negative, blood urea was 44 mg per 100 ml The urine contained nothing abnormal Radiography of the chest showed no abnormality Paul Bunnell test was negative Culture of the conjunctival sacs was sterile

---

[1] Russell S J M., MacArthur P *Lancet* 1950 i, 59

The clinical picture and investigations were typical of severe erythema multiforme

The patient was treated with aureomycin 250 mg 3 hourly by mouth for 8 days, and locally with lotio acid boric to the eyes and genitals Within 24 hours there was noticeable improvement in the condition of the eyes and mouth The speedy improvement was maintained, and he was discharged home 9 days after admission, showing only slight residual desquamation of the skin.

Although the patient was not severely ill his mucous membranes and skin were extensively involved, and he recovered in 9 days This compares with an average time of 3–4 weeks in other cases I have seen not treated with aureomycin

PROTHROMBIN CONSUMPTION DURING MENSES

SIR,—In your issue of Sept 30, Professor Baserga and his colleagues reported that in normal women with normal menses prothrombin consumption was constantly reduced during, and especially at the start of, the menstrual period In the course of a report [1] on the prothrombinopenic effect of penicillin, we recorded an increase in the prothrombin level during the premenstrual phase A systematic study of this problem has been planned

Beilinson Hospital Israel

Z LEWITUS

SALICYLATES IN ACUTE OSTEOMYELITIS

SIR,—The letter from Dr Kelemen and his colleagues (Sept 30) prompts us to mention some results we have reported [2]

Starting from the accepted principle that sodium salicylate inhibits hyaluronidase exclusively in vivo, one of us thought that such antidiffusive action might be promoted by liberation or production, under salicylate treatment, of anti hyaluronidase substances [3] The dramatic improvement in rheumatic diseases with 'Cortisone' and adrenocorticotropic hormone (A C T H), and the recognised remarkable antidiffusive activity of such hormones, caused us to investigate possible variations in the secretion of adrenal cortical hormones in patients under treatment with salicylates

We found that in guineapigs sodium salicylate in a daily dose of 0 075 g caused an increase of urinary output of 17 ketosteroids per day, the increase being maximal on the 3rd and 4th days and gradually decreasing with rather high levels on the 10th day After stopping the drug on the 20th day, the levels remained slightly raised With double dosage of sodium salicylate the effect was almost the same

Daily intramuscular administration of sodium gentisate in comparable doses evoked a slower and smaller increase in urinary output than that caused by sodium salicylate With both drugs we have observed a small but significant decrease in peripheral eosinophils and lymphocytes

These findings suggest the existence of a relation between salicylates and adrenal function These results should be considered together with those recently obtained by Shuman and Finestone,[4] who observed in man an increase of antidiffusive action during salicylate therapy, this they suggested was secondary to overactivity of the adrenal gland under adrenaline stress

MASS RADIOGRAPHY

SIR,—The facts given in Dr Hoffstaedt's art Dec 9 will be familiar to most workers in mass graphy, who will agree that, with limited resource yield or "dangerous" groups should receive p with special emphasis on patients referred by practitioners Many units have been followin policy since their inception

I should like to examine some of the stat in your leading article of the same date, which may cause misunderstanding The article say "mass radiography, as used at present, is expe This sentence is preceded by a statement that

> "the tuberculosis service needs much costly tion, it lacks new quarters and equipment dispensaries and chest clinics, more beds, more

and is followed by

> "some feel that we should not be spending s on finding new cases when we are not yet pr adequate treatment for those already found"

Presumably, it is to be understood that the could be spent to greater advantage in another w is not clear whether this refers to the £109 spent the very early case in routine surveys, or to the £l on the (somewhat more advanced) case referred general practitioner Although we now know t of finding an early active case of pulmonary tube by mass radiography, no deductions can be mad whether this represents good value for money deductions cannot be made until we know what is likely to come from spending the money on any proposed alternatives of "new quarters and equ for the chest clinics, more beds, and more sta seems unlikely that the expenditure of large s money on new clinic buildings would save the many patients

Large film radiographic apparatus is often wa used in clinics Two types of cases referred at commonly receive the same investigation, discrimination These are (1) the ill, or cl difficult, case, where a consultant's opinion is re and (2) the not ill case, with minor respiratory o symptoms, which the general practitioner sen radiography to exclude pulmonary tuberculosis on the first group that the consultant's skill a expensive full routine investigation, including films, sputum examination, blood sedimentatio and blood counts, should be concentrated F routine to be applied indiscriminately to the second where all the doctor needs is a report on a 35 m is a waste of public money This ritual not only money but also costs lives, for general practi well know that they must hesitate before re "suspects" for radiography, because the sym "indicating" the need for these investigations common that if they did, the chest clinics wo swamped with demands they could not mee giving general practitioners access to mass radiog reports, consultants would be freed to give attention to the management of their tuberculou and the investigation of clinical problems

On this service it costs £50 to find a case of pulmonary tuberculosis Is this expensive? If we by early diagnosis, shortened the stay in a sanat at £8 per week, by only six weeks, the service ha for itself Such cases can be prevented from bec infectious, or can be sooner rendered non infec and the patients can be restored to their jobs inst becoming deteriorating invalids Often they c treated effectively at home without recourse to therapy in expensive institutional beds Early can be treated in sanatoria with more patients per than is possible with the later cases needing lon in bed mersion.' apparently the cubicle was only partly full water

The main interest of the report seems to centre on the mount of air-space unfilled by the water, and it would of some interest if this apparent discrepancy could be ared up

Hanmore. R W MONCRIEFF

PULMONARY HYPERTENSION IN MITRAL STENOSIS

SIR,—In their paper of Dec 30 Dr Bayliss and his lleagues confirm the finding of Hickam and Cargill[1] at in subjects with mitral stenosis the pulmonary terial pressure may rise with exercise without any crease in cardiac output They accept the argument the American workers that such rises cannot be tributed to the resistance offered by the mitral valve This argument overlooks the fact that since blood flows rough the valve only during diastole the effects of ear rate must be considered For example case 15 ad a resting rate of 58 per minute, and an exercise rate f 145 At rest the total diastolic time per minute would e about 36 seconds during exercise it could scarcely ave exceeded 12 seconds. Approximately the same uantity of blood was passed through the valve in both hese periods, and a higher pressure would be required to ffect this in the shorter time.

The stenosed mitral valve causes turbulence, as evienced by the diastolic murmur and is unlikely to act s a linear resistance. One would in fact expect the ressure-drop across the valve to be proportional to the quare of the flow rather than to the flow itself Thus n the case quoted the pressure across the valve during iastole might have increased some ninefold with exercise n spite of an unchanged cardiac output. It is clear that t cannot be assumed that the left auricular pressure emained unchanged.

I do not wish to deny that changes in pulmonary arteriolar tone may occur under the conditions of the experiments, but merely to point out that they cannot safely be inferred from the data

St Thomas's Hospital,
London S.E.1 A C DORNHORST.

ALARMING NAMES FOR HOSPITALS

SIR,—Your annotation last week on the need for a humane psychological approach to hospital names with regard to their repercussions, so often tragic, on the patients and their families and friends recalls a similar personal experience in relation to the old 'tuberculosis dispensaries.'

I had observed that the term was associated with great opprobrium by the ordinary patient whose dread of "consumption" frequently necessitated a more tactful explanation by the general practitioner, to persuade him to avail himself of the facilities provided by the dispensary In 1929 the local authority with which I have been associated fell in with my suggestion to replace this unfortunate designation by that of 'chest clinic,' and they have now the satisfaction of knowing that their pioneer change of title has been adopted throughout the tuberculosis service of the National Health Service by all regional boards

I have outlined in my book on Chest Disease in General Practice and, more recently in a paper on the Tuberculosis Service in the National Health Service[2] the machinery that exists and the wider objects visualised in relation to chest disease in general and to pulmonary tuberculosis in particular These embrace prevention, diagnosis treatment research, and undergraduate and postgraduate teaching

The radical change so far as the tuberculosis dispensary is concerned is now accepted, and the patient has been given peace of mind Undoubtedly the tuberculosis (chest) service leaves much to be desired but its potentialities for the future are unlimited.

On analogous lines, a more humane approach to the designation of hospitals with such alarming names as cancer and incurable should be possible Such a change need involve little inconvenience or financial difficulty and would no doubt contribute to greater coördination in the hospital service as a whole

London W 1 PHILIP ELLMAN

SIR,—From a long term viewpoint there is much to be said for explaining to the public the meaning of words like cancer and consumption But it will take very many years before the meanings are understood as we doctors understand them It is a matter of urgent simple thoughtfulness that alarming names should be abolished 'The Brompton' has given an excellent example by dropping the reference to consumption from its notice-board. It would be much easier for general practitioners to persuade patients needing special treatment to avail themselves of the special facilities without dangerous delay if the names were no longer alarming

It is to be hoped that the medical and lay members of the committees of hospitals with unfortunate inheritances in their names will read your annotation

Guy's Hospital,
London, S.E.1 RONALD MAC KEITH

HEPATITIS

SIR,—Your leading article of Dec. 30 and a paper by Ballard F Smith[1] of Buffalo, prompt me to address you

Dr Smith describes his experiences when dealing with cases of infective hepatitis among service personnel at Fort Clayton Hospital In July 1949 he noticed a high incidence in men who had been tattooed during the period usually accepted as the limit of incubation for homologous serum or syringe-borne hepatitis—40 to 160 days.

While serving on the staff of a large military hospital in Germany during the summer of 1947 it was pointed out to me while visiting one of the hepatitis wards, that amongst the patients admitted during the previous ten days no fewer than 6 had been tattooed on the same day and by the same artist rather less than four months before. Captain W T Hendry who had made the observation was encouraged to follow it up with the result that within a short space of time over 40 cases had been collected, all of which might well have been infected in this way As in Dr Smith's cases the disease differed in no way from other cases of infective hepatitis being treated in the hospital. In all cases syphilis and syringe episodes of all kinds were excluded

Captain Hendry visited the artist who had in every case been responsible for the decorations, and was fully satisfied that the technique used was such as to make easily possible the transfer from man to man of virus-infected blood I had considerable difficulty in restraining my colleague, who was anxious to submit his own epidermis to the artist's needle in his attempt to establish the relation between tattooing and hepatitis.

A more complete investigation was planned but difficulties arising from the constant release of patients at the end of their term of military service made this almost impossible. A number of recently tattooed men were, however, asked to write to Dr Hendry in the event of jaundice appearing and they were provided with special cards for this purpose I am not aware, however, whether there were any results from this

Our experience in 1947 would seem to support the opinion of Dr Ballard Smith—that in tattooing we have yet another way in which the infection of hepatitis can be, and I believe often has been spread.

STUDY OF DELINQUENCY

SIR,—I had not expected that my mild remonstrance (Dec 2), now described as a violent onslaught, would have made any dent in Dr Stott's stereotype of the psychiatrist as an old fashioned, incompetent, and pompous father figure But in face of the implied shortcomings of psychiatric practice described in Dr Stott's paper to the psychologists (Nov 25), I wanted to record my disagreement with his assertions

"' Cet animal est méchant—lorsqu'on l'attaque il se défend " Surely this is a simple enough explanation of the ' psychiatric onslaught " without the elaborate rationalisations of projected guilt feelings, scapegoating, Uncle Paul Reiwald, and all One wonders whether Dr Stott has even heard of child psychiatrists, or of the fellowship scheme of training in child psychiatry organised by the former Child Guidance Council and later by the National Association for Mental Health It would be difficult to imagine a more realistic training than that provided by the scheme, which incorporates the new techniques demanded by Dr Stott

Dr Stott omits from his list of social practitioners the school medical officer, it has been my experience, during 12 years of work in child guidance clinics, that the school medical officer is on his toes to "spot" the maladjusted child and is quick to refer him, and to demand priority for him, at the child guidance clinic As for psychiatric reports to the courts, Dr Stott must know quite well that, whatever the provocation, publication of these confidential reports would be impossible

His position to assess the validity of psychiatric judgments is perhaps not so unique, even I, as a psychiatrist responsible for treatment of delinquent boys in an approved school, have shared to some extent the facilities he has enjoyed of reading many psychiatric reports from a number of different sources And, Sir, I cannot confirm his general conclusions about the uselessness of these reports Taken as a whole, the reports have been extremely useful, fair assessments of the situation and sober forecasts of the boy's future, of course there have been the occasional exceptions, but I do not base my generalisations on the odd example

Bristol

FRANK BODMAN

SIR,—It is good of Dr Stott to admit (Dec 16, p 821) that the present revolution in clinical psychology was medically inspired I wonder what the academic psychologists were doing at the time Perhaps he should learn from this that the art of clinical medicine gives its votaries something more than technical knowledge, anatomical, psychological, or otherwise

A little psychology can be a dangerous thing I do not know that the crude mistakes made by bad psychiatrists are any worse than those made by bad psychologists We psychiatrists can be our own severest critics let Dr Stott leave them to us to speak to, and let him put his own house in order

I would accuse Dr Stott in his propagandist zeal of grossly over simplifying the problem of delinquency His remedy is far too easy From my experience let me repeat a word of advice Modern personality psychology may be perfectly straightforward in a study or an arm chair, but its practical application is a very different matter and needs something more than mere knowledge For example, his simple panacea of fitting people into a "belonging group" is very nice on paper, but let him try to put it into practice and he will find, as others have found, that it is not as easy as would appear In fact it is *because* they cannot feel secure and cannot find a satisfactory belonging group that so many cases need our help (I emphasise satisfactory, for some of the delinquent groups may make its members feel more secure but can hardly be tolerated by society)

Religious bodies have taught even more profound idealisms for many centuries, but have to admit that teaching, or preaching, alone is inadequate It is this something more which one gets from clinical experience with patients, and which is the great asset of a proper medical qualification One would hope that before long those who wish to be clinical psychologists will have to undergo something analogous in their training, this would make one more confident in handing over cases to their care

There is plenty of room for medical and non medical personnel in this field, and I am sure it would be happier if each of us could work for a better training of both each within his own branch of the profession

Leeds

H EDELSTON

ENDURANCE FEAT BY A YOGI PRIEST

SIR,—Dr Vakil has given a most interesting account (Dec 23) of the endurance of a Yogi priest sealed up in a 216 c ft concrete chamber Physiological considerations, however, do not explain away the mystery as easily as he supposes

It is not to be expected that a man sealed up in this way could use all the oxygen originally present Assuming a resting basal oxygen usage of 0 5 c ft an hour, or 0 236 litres a minute (a reasonable value for a normal man) and a respiratory quotient of 0 8, at the end of 56 hours in a gas tight cubicle of 216 c ft capacity, the atmosphere would contain only 7 8% of oxygen and 10 4% of carbon dioxide In this calculation no allowance has been made for the temperature, pressure or water vapour content of the gas in the chamber, because the data are not available, but probable values for these quantities would lead to the expectation of 6 6% of oxygen and 11 4% of carbon dioxide It would be a very extraordinary thing if a human being could be shown to survive for many hours in an atmosphere slowly approaching this composition Of course the Yogi priest may have had a lower metabolic rate than the 1700 calories per day which these figures assume, and there may have been a certain amount of gaseous diffusion through the walls of the chamber, or adsorption of carbon dioxide by the walls

When it comes to pouring water into the cubicle there seems to be a discrepancy in the figures, for 1400 gallons will not go into 216 c ft, and it is hardly credible that even a Yogi priest has a negative volume I suppose a good deal of the water soaked into the concrete walls

It is greatly to be hoped that Dr Vakil's article will stimulate others to investigate and report similar cases It would be very valuable indeed if an analysis could be made of the atmosphere in the chamber just before the release of the subject Until such figures are available we cannot be sure whether there is a real or only an apparent mystery

Department of Physiology,
The Queen s University of Belfast

A D M GREENFIELD

SIR,—I have read with considerable interest Dr Vakil's account, but its value as a scientific report is diminished by the inclusion of one or two inconsistencies, notably

1 The total air capacity of the cubicle ' worked out at 216 c ft Such a volume would hold 1346 gallons of water, whereas about 1400 gallons of water was introduced

2 Despite the apparent overfilling of the cubicle the priest is reported to have been in a state of almost complete

Misgiving centres chiefly on the salary of the assistant dical officer of health When taxation levels and the st of living are taken into account, a maximum salary £1150 in 1950 does not compare very favourably with maximum of £700 in 1929 Two other points of mparison are also available now which were not ailable then—namely, salaries in the hospital service d earnings in general practice The assistant medical ficer will undoubtedly look with some envy, as will the nior medical officer in charge of a school medical or aternity and child welfare department, at the current nancial status of his late colleague the chest physician e will also await with interest the promulgation of the lary scales for his colleague the public health dentist, ow under the consideration of another Whitley mmittee

Despite these doubts, the British Medical Association nd the Society of Medical Officers of Health are to be ngratulated on the skill and pertinacity with which ey pursued their claim The public health service, it has not gained all that was hoped, has nevertheless ained much by their efforts

Smallpox at Brighton

Up to 6 P.M on Jan 1 there had been 11 cases of mallpox in Sussex, with 1 death Of these, 10 were Brighton residents and 1 belonged to the neighbouring rban district of Portslade Surviving cases are now at ong Reach Isolation Hospital, Dartford, where 4 were dmitted on Dec 29, 2 on Dec 30, 3 on Dec 31, and 1 on Jan 1

The infection appears to have been brought into the ountry by an R A F officer, who reached Leuchars, Fife, by Service plane from Karachi, on Nov 27 On Nov 29 he travelled by train to Brighton and felt ill during the journey He went to bed on reaching his destination and later a sparse rash developed, which did not come under medical observation The minor nature of the complaint in this case is explained by the patient's high vaccination state, diagnosis in such a case is particularly difficult

This initial case passed on infection directly to a young woman and to a man, aged 53, in the house where the officer was residing in Brighton, the man died of hæmorrhagic smallpox on Dec 29 Indirectly, a woman and a man at Portslade were infected Unfortunately, the condition of the first woman patient, admitted to the Bevendean Infectious Disease Hospital, Brighton, on Dec. 18, was misdiagnosed until Dec 28 This delay allowed the dissemination of infection in the hospital, and 3 nurses there have now fallen victims Of these nurses, 2 had never been vaccinated, and the outlook in these cases is grave, the 3rd nurse was vaccinated only once, when a child The hospital has been in quarantine since Dec 31

The staff of a Brighton laundry is also involved, the officer s clothes were sent there on Dec 13 So far there have been 3 cases from this source 2 are women who dealt with the clothing at a receiving branch, and the 3rd is a sorter at the main laundry

It is difficult to forecast the likely extent of this outbreak because

1 The initial case was so modified that the patient was able to travel to and from Scotland in an infectious state

2 The second case remained in an ordinary infectious diseases hospital for 10 days during which no special precautions were taken The poor vaccination state of some members of the staff there aggravates the risk In this connection attention is drawn to the memorandum R.H.B (50)75 issued on Aug 17 1950

3 Infection in a laundry opens the way to further spread

To minimise these risks all possible action is being taken to trace and vaccinate all known contacts both in England and Wales and in Scotland Nevertheless special vigilance must be maintained throughout the country to detect the disease in casual contacts who have not come under surveillance Although there are possibilities of spread, so far secondary cases have occurred only in the direct line of contact No cases have been reported outside the Brighton area

Influenza

There has been a marked prevalence of influenza in Scandinavia, where a virus has been isolated that is not unlike the A prime strain which occurred in this country in 1949 The disease, which has been mild but with a high attack-rate, appeared first in Sweden and then in Denmark and Norway A high incidence of influenza has also been reported within recent weeks from certain parts of the U S.A, Northern Spain, Sardinia, Persia, and elsewhere

In the absence of notification of influenza the incidence of pneumonia cases and of deaths from pneumonia and influenza are used as a guide to the prevalence of the disease The following figures relate to the great towns of England and Wales

Week ended	*Pneumonia (including primary and influenzal)*		*Influenza deaths*
	Cases	*Deaths*	
Dec			
9	347	236	34
16	274	283	33
23	363	350	54

In England and Wales notifications of pneumonia numbered 573 in the week ended Dec 9, 684 in the week ended Dec 16, and 647 in the week ended Dec 23

These statistics afford no evidence of any serious influenza epidemic, but in the last week or more this disease has been very prevalent in the North-East, where a number of large towns have been hit, including Sunderland, Durham and Newcastle upon Tyne It seems likely that the disease has been introduced to this area from Scandinavia, and it may well be that laboratory studies, when completed will show the virus strain to be identical with that in Scandinavia The disease in the North East seems quite distinct from the so called influenza which is at present widespread in other parts of the country The infection may spread southwards in the next few weeks

Poliomyelitis

In England and Wales notifications of poliomyelitis in the week ending Dec. 23 were paralytic 38 (82), non-paralytic 15 (25) total 53 (107) The figures in parentheses are those for the previous week, compared with which there has been a decrease of 54 cases Uncorrected notifications for the corresponding week in 1947 and 1949 were 60 and 81

Total uncorrected notifications for 1950 up to and including the week under review are 8643 The corresponding figures for 1947, 1948, and 1949 were 9147, 2356, and 6791

Food-poisoning in Kendal

An outbreak of 124 notified cases of food-poisoning occurred in Kendal and south Westmorland during the three days before Christmas

The outbreak was due to staphylococcal infection of jellied brisket and jellied veal prepared on the premises of one pork-butcher in Kendal About 150 lb of these meats was sold, mostly in 1/4 lb and 1/2 lb orders, to several hundred customers The meats had been prepared on Dec 18 and 19, and sale was stopped on Dec 23

Clinically the features were onset 2–4 hours after ingestion, sharp abdominal pain, severe diarrhœa, and in most cases vomiting Usually there was no fever Although there was some initial collapse in elderly patients, recovery was complete within 24 hours 3 patients developed urticarial rashes, including a breast-fed baby whose mother had eaten the meat 1 asthmatic patient developed œdema of the feet and ankles

The first cases were notified on Dec 22, 85 patients and staff of the Westmorland Sanatorium, at Meathop, having fallen ill after an evening meal the previous day, in this institution about 55% of those at risk developed symptoms On Saturday, Dec. 23, notifications were received of wider spread to Kendal and the surrounding areas of south Westmorland, Windermere, and north Lancashire All patients had eaten jellied meats from the same shop in Kendal

An appeal for prompt notification of cases was broadcast by the B B C in the 1 P.M news on Saturday,

Public Health

SALARIES IN THE PUBLIC-HEALTH SERVICE

Born after a long gestation, not free from complications, Whitley Council Medical Committee "C" last spring began the reconsideration of public health medical salaries Some four months of negotiation brought out the differences, on matters of principle, between the staff side, ably represented by the British Medical Association, and the management (local authority) side of the council These differences proving irreconcilable, the dispute was referred to the Industrial Court, at whose hearings during four days in October both sides were represented by counsel The award of the court, which affects the salaries of 2000 local-authority medical officers, has now been published and was briefly noticed on p 918 of our last issue

The awards made operate from Oct 1, 1950 They replace the agreed scales formulated in 1929 by the committee presided over by Lord Askwith These awards had in the interval been modified, first by the inclusion of a war bonus of £60 in the lower salary ranges, and then in 1946 by the addition of 30%, 20%, and 10% to salaries whose minimum commencing points on the Askwith scale were respectively under £700, over £700, and over £1000 The final agreed revision took place in 1947, when the percentage additions to the basic Askwith minimum were increased respectively to 35%, 30%, and 25%

For assistant and senior medical officers the court has made the following awards, against which we show the claims of the staff side and the offer of the management side

	Staff side claim	*Management side offer*	*Industrial Court award*
Assistant medical officer	£960 × 50–1680	Grade I £750 × 50–950 Grade II £900 × 50–1100	£850 × 50–1150
Senior medical officer *	Minimum (depending on population) £1680 × 120–2160 Maximum £2040 × 120–2520	Grade I £1150 × 50–1350 Grade II £1300 × 50–1500 Grade III £1450 × 50–1650	£1250 × 50–1650

* To be appointed only in areas where the population exceeds 250 000

The awards for medical officers of health are set out in the accompanying table

The court has not fixed salary scales for deputy medical officers of health, divisional or area medical officers, or officers holding mixed appointments These are left for joint negotiation between the parties, with a right of reference, failing agreement, to the Industrial Court

Part time medical officers of health are to be paid in accordance with the Spens formula in respect of consultants Holders of combined appointments are to receive £100 per annum above the appropriate salary scale for the total population of the combined districts The method of assimilation to the new salary scale is laid down and will be readily accepted as fair A "no detriment" clause and sick pay scales are included, but discretion is given to count service with one authority on transferring in the same grade to that of another, in fixing the appropriate commencing salary The undertaking of teaching duties and the disposal of any fees therefore are within the discretion of the local authority

Under the Askwith agreement salaries could be exceeded in particular cases at the discretion of the employing authority In the case of assistant medical officers this was done by several authorities, notably (for different reasons) Lancashire and London. The only dictum of the new award on this point is as follows

> "In addition, if a local authority in the exercise of the discretion permitted under the Askwith agreement appointed a particular officer at a salary in excess of the minimum then current, the local authority shall in assimilating that officer to the scale now awarded fix his starting point at a similar amount above the new minimum, provided however that the maximum of the new scale shall not be exceeded in such cases except at the discretion of the local authority"

These words are important They offer a clear method of avoiding hardship to existing officers and allow progressive authorities and those in whose areas (as in London) the cost of living is high to continue their lead or to offer partial compensation for local circumstances What is not at present evident is whether this differential advantage may be applied to new appointments, but it is to be hoped that in this matter the authorities concerned will, with the agreement of Committee "C," maintain their enlightened policy

On the whole, the awards represent tangible salary gains to the public health service When compared with what the management side felt able to offer, they fully justify what was in effect an appeal to arbitration. The medical officer of health may reasonably feel that his work is now to be remunerated on a basis which does represent his specialist qualifications and training and which does bear some relation to that of his clinical peer, the consultant On the other hand, the local authorities may also feel some satisfaction that (as the table shows) the maximum salaries of their chief officers are still closely related and that the team work so essential in local government will not, therefore, suffer from personal rivalries The varying scales of salary for populations of the same area will also help local authorities both to take account of local circumstances (as for instance in a county borough and an urban district) and to reward individual merit This principle is a new one in its application to public health salaries but there seems little reason to fear that local authorities will exploit it by always offering the lowest of the possible ranges

SALARIES OF MEDICAL OFFICERS OF HEALTH

Population not exceeding	Claim by staff side	Population not exceeding	* Offer of management side		Award of Industrial Court	
			Minimum of salary scale between	Increments	Minimum of salary scale between	Increments
50 000	1800 × 120 to 2280	75 000 100 000 150 000	1250 and 1650 1350 and 1850 1550 and 2050	4 of 50 5 of 50 5 of 50	1450 and 1650 1550 and 1850 1750 and 2050	4 of 50 5 of 50 5 of 50
100 000	1920 × 120 to 2400					
200 000	2160 × 120 to 2640	250 000	1750 and 2250	2 of 100 1 of 50	1050 and 2250	2 of 100 1 of 50
300 000	2400 × 120 to 2880	400 000	2000 and 2500	2 of 100 1 of 50	2200 and 2500	2 of 100 1 of 50
500 000	2640 × 120 to 3120	600 000	2100 and 2700	3 of 100	2300 and 2700	3 of 100
750 000	2880 × 120 to 3360	600 000 +	At discretion		At discretion	
750 000 +	3120 × 120 to 3600					

* This offer is the same as the scales agreed by the Joint Negotiating Committee for chief officers of local authorities It applies to accountants and treasurers engineers and surveyors chief education officers, and architects in charge of separate departments

orceful and pregnant minutes Everywhere he went he timulated interest and activity He created he improved he mprovised he did everything that was possible in war time o fill the existing gaps and to strengthen the weaker labora ories His efforts were crowned with success, and by the ime the regional hospital boards took over control the struc ure he had raised was ready to be incorporated as a permanent art of the National Health Service

Panton s contribution, however, was more than merely idding to the existing system He raised the whole tone of pathology, and contributed substantially to the progressive lifferentiation that occurred during the war years between he curative and preventive sides of his subject Once it became clear that clinical pathology was to be organised under he new Act on a regional basis and public health bacteriology on a national basis, he insisted that the two groups of laboratories should work side by side complementing each other in the provision of a functionally unified pathological service Panton was simple direct, fearless unselfish, unassuming unpretentious, and absolutely loyal, he inspired affection and respect among both old and young and he probably contributed more than anyone else to the present widespread distribution of pathological facilities that the country now enjoys

S C D also pays tribute to him as an administrator who never forgot he was dealing with people

"In the course of building up the Emergency Medical Service in hospital pathology Panton was called upon to deal with and to some extent to shape the destinies of many men and women He was an able organiser but his exceptional quality lay in that he never failed to remember that those whom he had to fit into his organisation were human beings all with their own personalities and each presenting a peculiar and unique case he was keenly interested in them all and to them always readily accessible all who approached him were sure of a sympathetic hearing and a careful consideration of their problems

Despite advancing years Panton never spared himself, and when in 1948 the change-over to the National Health Service took place, he was at the centre to facilitate the transition Only when this had been done did he retire, but, as events have proved, he had pushed himself so hard that he no longer had the health to enjoy the rest which he had earned so well

S P B, to whom we are indebted for much of this memoir, writes

'The account of his achievements shows a glimpse of his make up He was a man of great ability and excellent intellect, yet he was not outstanding as a teacher, his lectures were interspersed with marvellous touches of humour but unfortunately these escaped all but the first few rows of his audience He did some good original work, notably on staphylococcal toxins and hæmatological problems—enough at any rate to show that given the opportunity he would have made valuable contributions to medical knowledge It could not be claimed however that he was a born investigator, though his advice on a research problem could be of the greatest value and one always felt that something really useful would emerge from a discussion with him

'Until the war came with his appointment as consultant to the Ministry he was hardly known outside the London He was not a member of any of the societies which had to do with pathology and even towards the end, when he was at last appreciated at his full merit and he was offered honorary membership in the Association of Clinical Pathologists, he declined. Honours meant absolutely nothing to him and the one that came his way—a knighthood in 1945 for his services to pathology—he accepted because he thought the London Hospital would wish him to

'Prowess in athletics was not one of his achievements yet he delighted in the countryside enjoyed walking, and was or had been an enthusiastic fisherman. Above all he enjoyed his garden and he spent many a happy hour working in it though his botanical knowledge was defective and the methods he employed were sometimes unorthodox (On one occasion he transplanted a well grown apple tree in full bloom and what was the more surprising was that it survived the insult) None the less Otter s Pool was his chief relaxation and he looked forward to tending it in his retirement and to receiving there the visits of all those pathologists for whom he had worked so hard It is sad to think that all that is no more

J J A. also writes of Panton's retirement, and tells how in the intervals of the landscape gardening he compiled reminiscences of medical life looking forward to seeing appear this sprin

When they do appear they will introduce a whimsical personality to the wider world outside fession and amplify and crystallise many memo who knew him in real life For Panton was suc man once you got behind the barrier of his shyness a admitted to his friendship A tolerant twinkle in blue eyes betrayed the kindly observer of human wea and told of the quiet fun he got out of his freque apparently heated contests with authority For he individualist like his grandfather, William Frith the painter of *Derby Day* and he fought for what he considered right whenever he came up against authority—whether as a schoolboy at Harrow, an undergraduate at Cambridge a lecturer in London or an adviser at the Ministry of Health during the war

And a last tribute from F C O V runs

'Panton was undoubtedly conscious of his own great gifts in which strength of character was combined with an acute and wide understanding, but his essentially formidable personality was tempered in a most attractive way by a great sense of humour a very real sympathy and comprehension of those with whom he worked, and with a hatred of bombast in any form This last trait was presumably responsible his well known inaudibility at lectures which once reached me at lunch in ho was holding forth at a neighbouring tal think of something worth saying as loud was in fact a master of the spoken and a student he edited the hospital gazett writing most of it himself as he once told at a loss for the right word or phrase, a years he wrote stories for his grandchildr reminiscences This artistic facility, deriv his grandfather Frith, may have made impatient of the details inseparable from laboratory, though no one was more fertile i advice to others He was at his best by the investigation of a difficult case, and it was his of the needs of the clinician that led him to dev of organisation primarily to building up a routi service, first at the London and later throughout

CYRIL HOCKEN TEWSLEY

C.M.G, M.A N.Z., M.D EDIN, F R C.P E, F R C.

F.R A C P

THOUGH Dr Tewsley was born, received his early tion, and spent most of his professional life Zealand, he had, during his student days in Edinb and his war service, made many lasting ties with this country

The son of the late Henry Tewsley, he was born in 1878 in Dunedin From the local high school he went to Otago College, and he took his M.A. in 1901 before beginning his medical studies at Edinburgh He qualified in 1906 and after holding house-appointments at the North Riding Infirmary, Middlesbrough, took his F R C.S and his M D in 1909 before returning to New Zealand There he settled in general practice in Auckland, and in 1912 he was elected to the staff of the Auckland Hospital

[Alan Kaby

As soon as war broke out in 1914 he joined the New Zealand Medical Corps, and he left on active service with New Zealand s main body of troops He took part in the landing at Gallipoli, and he was later in charge of the convalescent hospital at Hornchurch Essex On demobilisation he settled once more in practice as a general and consulting physician in Auckland, where he was medical officer to the police force and prison, and chief of the medical staff of the St John Ambulance Association. Last August he was promoted to be a commander of the Order of St John in New Zealand. He was also a vice-president of the Royal Australasi College of Physicians and a past president of the Auckl and there was an immediate response The suspected food still unsold was surrendered by the manufacturer, and a warning not to eat jellied meat purchased from this shop since Dec 20 was broadcast by the B B C in the northern news on Saturday evening at 6 15 P M and repeated at 6 20 P M

The prompt publicity by the press and the B B C was undoubtedly the major factor in preventing the wider spread of the food-poisoning, for it was found that many people were keeping the meat for use over Christmas The Sunday newspapers repeated the warnings, and no onset later than Christmas Eve was reported It is expected that further cases with an earlier onset will be reported, and it is likely that a large number of cases will remain unnotified

Staphylococcus aureus was cultured from samples of the jellied meats sold and unsold, from the jelly stock prepared at a stage in manufacture before it is added to the brisket and veal, and from a skin lesion on the hand of a food-handler involved No presumptive connection can be made between this handler and the infected meat until the results of typing the organism are received from the Central Reference Laboratory All other samples of food and drink from patients negative for food-poisoning organisms The gel powder used for thickening the meat stock was like negative Circumstantial evidence pointed to an dental infection of the jelly stock during the of preparation of the pressed brisket and veal, a the slow-cooling technique practised in manufac favoured active growth of the organisms, particu in the centre of each mould It is not yet possib assess the relative responsibility of toxin and li organisms *in the production of the gastro-inte* irritation, but it was felt that the toxin was the m likely factor

Routine cleansing and disinfection of the premi was carried out, and all utensils were steam sterili Lectures on food-handling hygiene were given, three film-strips of the Central Council for Hea Education were exhibited, to the management and st of the manufacturing firm, and several modifications the technique of manufacture were advised A ch of manufacturing methods of prepared meats in oth similar premises in the area is in progress, to mini the risk of such infections being repeated

Obituary

PHILIP NOEL PANTON

K T, M A, M B CAMB

On Dec 27 Sir Philip Panton died at his home at Bourne End after a short illness, his retirement had lasted little more than a year Many will have heard this news with real sorrow, for, besides his colleagues and numerous generations of students at the London Hospital, he was held in high esteem and affection by hospital pathologists up and down the country, whose working conditions and status he had done so much to improve

[Walter Stoneman

Philip Noel Panton, son of the late James Panton, was born 73 years ago at Wareham in Dorset He was educated at Harrow and Trinity College, Cambridge, taking the natural sciences tripos in 1899 At St Thomas's Hospital, where he was contemporary with H R Dean and A E Boycott, he was grounded in pathology by Shattock and Dudgeon, and the inspiration given him by these two great teachers was largely responsible for his decision to specialise in this branch of medicine

Qualifying in 1903, he held house-appointments at Addenbrooke's Hospital, Cambridge, and then returned to St Thomas's to work with Dudgeon as a Louis Jenner research scholar Later with the Gilson research scholarship of the Society of Apothecaries he continued his specialist training, and when he was appointed assistant director of clinical laboratories at St Thomas's Hospital, his election to specialise in what, for want of a better term, is known as clinical pathology was made He held this post for only a short time, for in 1908 he went to the London Hospital as director of the clinical laboratory, a newly made post which he was to hold with distinction until 1946

This new department, started largely at the instigation of the late Mr Frank Kidd, began in a modest way, with one small room and a single technician Its exact relation to existing departments was not easily defined, but thanks to Panton's professional and statesmanlike qualities the early difficulties were overcome and it continued to develop and expand In 1934 he became director of laboratories in the hospital, which included the laboratories of the departments of chemical pathology and of bacteriology The creation of a division of pathology which would be a geographical whole readily available to the clinician, was one of his goals, and he lived to see its accomplishment Another objective which he set himself was to expand the research activities the hospital laboratories The staff of the clin laboratory had not the leisure to use all the mater reaching them, and he realised that this could only done by the appointment of men with research abil freed from all routine duties Thanks to the generos of his friend the Rev M S Courtauld, this was acco plished in 1926 by the formation of two Freedom resear fellowships and a Freedom research studentship

If Panton had achieved no more than this he mi have been well content, but his major work was yet come With the outbreak of war in 1939 the Lon Hospital's laboratories were closed except for a sm clinical laboratory, and the staff and apparatus w sent to equip new laboratories in the two sectors pla under the hospital's ægis Panton was largely respons for planning this transfer, and he was instrumental having made a complete register of qualified patholog and laboratory technicians through the country At t outset he directed the laboratories of a sector, but it w early realised that the Ministry of Health needed adviser on hospital pathology and Panton was obvious choice

Of his work at the Ministry W J writes

"More than anyone else, Panton established clin pathology as an integral part of our hospital service. consultant adviser to the Ministry of Health he saw to it the upgrading of hospitals in the Emergency Service inclu adequate provision for laboratory work In coöperation w the medical branches of the fighting Services and the Med Research Council, he organised a scheme for the trainin pathologists and arranged for the posting of patholog where they were most needed He scrutinised every labora plan and visited regularly every laboratory centre in country Needless to say he knew personally every mem of the service During the war he travelled thousands of m on duty, often in great discomfort, for he always beli that he could accomplish much more by personal con than by *writing letters from Whitehall* He encour regional meetings of pathologists and arranged for re sentatives from the regions to meet him regularly in ministry for the discussion of matters of common inte At times he rebelled against the slowness of the departme machine but he had a great sense of humour and usually his own way in the end *By laying the foundations of a sc* laboratory service in the hospitals of this country Sir P Panton has provided his own permanent memorial"

From the first, Panton had the vision *to see bey* an emergency service Believing firmly that an essen to good medicine was good clinical pathology, he himself to create an adequate service of hospital pathol throughout the country G S W, who shared in arduous task, recalls how Panton performed it

"He travelled round continually, observed the inadeq arrangements that so often existed for providing the clini with the laboratory help to which he was entitled, embodied his conclusions and recommendations in a serie viding assessed values for each of the foodstuffs, selected om standard tables of analysis by an estimate of the optimum aily human requirement of each vitamin and mineral The arts in this way provide an immediate visual assessment of e value of the foods judged by human requirements The lea is ingenious, and will appeal to all who do not take kindly large tables of figures

THE TROMBONIST'S A P

THE trombonist referred to by a Peripatetic Correspondent n Nov 11 (p 539) writes "Readers may like to know that y artificial pneumothorax causes no unusual sensations when play my trombone ' The word 'blowing" is a misnomer hen applied to playing a brass instrument The player erely projects a thin stream of air against his lip, which in rn vibrates the air column inside his instrument With orrect breathing the diaphragm takes the larger part of the train and the lung is not greatly overtaxed as was shown y my doctor s ingenious experiments In your next issue Nov 18, p 593) another correspondent suggests that the first rombonist has a more tiring part than his colleagues in the econd Symphony of Sibelius I cannot agree with this iew It is true that he has a short solo passage of three bars efore the coda but this is in the most comfortable compass f the instrument and is of equally comfortable dynamics he maximum effort called for in this work is undoubtedly n the solo commencing 18 bars from the end of the symphony, here all three trombones play the melody *fff* in unison his is one of the most exhausting passages in the symphonic epertoire

---

University of London

At recent examinations for the academic diploma in medical adiology the following were successful

M M Craig (diagnosis) Hussain Syed Ali, R J Dickson A W Reghers (therapy)

On Friday Jan 26, Prof A. W Downie will give a lecture at the London School of Hygiene Keppel Street, W C 1, on Infection and Immunity in Smallpox On Feb 7 and 8 at the School of Pharmacy, 17, Bloomsbury Square W C 1, Mr E Lester Smith, D SC, will speak on the Isolation, Properties and Functions of the Vitamins B_{12}

On Feb 26, at the London School of Hygiene Dr Engelbreth Holm professor of pathological anatomy in the University of Copenhagen, will lecture on Folic Acid and Growth of Tumours especially Rous Sarcoma All the lectures will be given at 5 30 P M.

The title of professor of clinical pathology has, as announced ast week, been conferred on Dr Montague Maizels reader n clinical pathology at University College Hospital medical school

Dr Maizels took the Conjoint qualification from Guy s Hospital n 1920 and his M B Lond two years later He acted as Anderson lemonstrator in clinical chemistry and medical registrar at Guy s before he was appointed pathologist to the Westminster Hospital During the late war he was director of the emergency blood trans usion depot at Maidstone He has published papers on the anion and cation content of normal and anæmic blood and on cation control in human erythrocytes

University of Liverpool

At recent examinations the following were successful

M.D—J W L Edwards Elizabeth Rees

M Ch Orth—N J Blocker L Bonnin V K. Drennan, K S Fan Henry J H Hicks T McSweeney F Machanik, J B Maloney M. R. Reddy A M Sallam H O Williams

Royal College of Surgeons of Edinburgh

At a meeting of the college held on Dec 20, with Mr W Quarry Wood, the president in the chair, the following were admitted to the fellowship

Sheroo Darabsha Bharucha R A. Bremner Leon Bryer, J C Campbell Mohendra Lal Chatterjee W Y Cornock Mohamed Fathi El Giziri, T G Evans R H Freeman D M. Hancock, W T Irvine, Gopal Krishna Robert Lipschitz Grant McIntosh J T Marcroft, A. R. Murison J R. Reid, Elia Gobrial Sarofim Aubrey Schiller B M. C Sedzimir T V Simpson, P C Steptoe A. E M. Stevenson, Frederick Viedge Thiagarajah Visvanathan C J Windsor

Royal College of Physicians of London

Dr H J Anderson will deliver the Goulstonian lectures on Tuesday and Thursday, Jan 9 and 11, at 5 P M., at the college, Pall Mall East, S W 1 He is to speak on Tuberculosis of the Pericardium

Faculty of Radiologists

The following candidates satisfied the board at the 1950 examination for the fellowship

A N Gaballa W S Holden G B Locke (radiodiagnosis), D G Bratherton B A Stoll R C Tudway (radiotherapy)

British Association of Plastic Surgeons

The following officers and members of council have been elected

President Mr A B Wallace (Edinburgh) vice-president, Mr R J V Battle (London), treasurer Mr R P Osborne (Liverpool) secretary Mr J P Reidy (London) editor Mr A B Wallace (Edinburgh) members of council Mr J N Barron (Salisbury) Mr G M FitzGibbon (Bristol) Prof T P Kilner (Oxford) Sir Archibald McIndoe (London) Mr J S Tough (Glasgow), and Mr Rainsford Mowlem (London) ex-officio as immediate past president.

Association of Psychiatrists of the Scottish Western Region

The following office bearers have been elected for 1950–51

Chairman Prof T Ferguson Rodger vice-chairman Dr A Dick, secretary Dr Hunter Gillies, treasurer Dr M. M Whittet Dr Gillies may be addressed at The Crichton Royal, Dumfries

King's College Hospital

Dr V F Hall has been appointed dean of the medical school in succession to Mr Harold Edwards Mr A. J Heriot succeeds Dr Hall as vice-dean.

Heberden Society

A clinical meeting will be held at the Westminster Hospital Medical School on Wednesday, Jan 24, at 4 P M Cases will include some demonstrated a year ago, to show progress Dr L E Glynn will show, for Dr W S C Copeman and Dr O A. Savage, a short film on the Therapeutic Effects of 'Cortisone'

International Hospital Congress

The International Hospital Federation is holding the seventh International Hospital Congress in Brussels from July 15 to 21, under the chairmanship of Dr René Sand The central theme will be the Care of the Chronic Sick and the Aged, and the speakers will include Dr E M Bluestone, director of the Montefiore Hospital New York, and Prof Pierre Delore, of the University of Lyons The federation may be addressed in this country at King Edward s Hospital Fund, 10, Old Jewry, London, E C 2

Blood Donors

In England and Wales gifts to the National Blood Transfusion Service in the quarter ended Sept 30 numbered 133 693, bringing the total for the first nine months of the year to 388,000—a new post-war record Over 31 000 volunteers joined the service in the September quarter This brings the total of donors to 398,000—a gain of nearly 10,000 in the quarter To keep ahead of the growing demand a further 190,000 donors are needed

Houses for Doctors

Housing authorities have been asked by the Minister of Health to help in securing houses for general practitioners In a circular the Minister expresses the hope that when a doctor s application to build his own house is supported by the executive council the local authority will consider the issue of a licence It would, furthermore, be helpful if in suitable cases local authorities "would be able to agree to provide a site by sale or lease It might be appropriate for the local authority to make a site available for the purpose on their larger estates Similarly, should a doctor apply to the local authority to rent one of their houses, the Minister trusts that the application will receive sympathetic consideration when it is supported by the Executive Council." When local authorities are considering the allocation of the tenancy of a house intended for occupation by a doctor, the executive council should be informed so that they can, if necessary, advertise the vacant practice It will be appreciated that the statutory functions of Executive Councils may be impaired unless there is the fullest possible co-operation between them and the local housing authorities " and on of the British Medical Association During the food'ar he served with the rank of colonel as A.D M S and ie northern military district in New Zealand th erly he became interested in the history of medicine, in he gave several pleasing addresses embodying his reanings

Dr Tewsley married a daughter of the late Dr P A idsay, of Auckland His wife survives him with two ns and three daughters

TIMOTHY GERARD DEMPSEY

M B N U I

r T G Dempsey, who died in Dublin on Nov 25 he age of 34, qualified at the National University eland in 1941 Two years later he joined the staff he Grove Park Hospital in London, and here he ne interested in clinical research on tuberculosis as associated with the first clinical trials in Britain *ara* aminosalicylic acid, on which he published a paper in our columns in 1947 Later he visited ontinent, America, and India, where he lectured is experience with P A S In 1948 he joined the of the Mayday Hospital, Croydon, where he ituted a new régime of treatment

M K writes "Dempsey inspired his co-workers n in their difficult task His charm endeared him to his patients red himself in his efforts onstantly over- on their behalf , but during long d his keen interest aracteristic humour was an inspiration d two young children

APPLICATION OF PSYCHOLOGY TO DERMATOLOGY

R. M. B. MacKenna
M.A., M.D. Camb., F.R.C.P.
PHYSICIAN IN CHARGE OF THE DERMATOLOGICAL DEPARTMENT, ST BARTHOLOMEW'S HOSPITAL, LONDON

Ida Macalpine
M.D. Erlangen, L.R.C.P.E.
ASSOCIATE CHIEF ASSISTANT IN THE DEPARTMENT

Six years ago one of us wrote a paper intended to focus attention on psychological factors in dermatology (MacKenna 1944). We now try to specify more precisely the psychological factors involved in the production and cure of skin diseases.

Ideally, this psychological and dermatological approach to skin disease should be a double approach made by a single clinician. For reasons of training this is hardly ever possible. Hence it is necessary to establish fruitful coöperation between the dermatologist and the clinical psychologist. This may seem a banal statement, but in reality there might easily enter into such common work a sense of rivalry concerning the scientific priority and validity of the two disciplines. Since some of the differences between the two approaches are fundamental, they will be discussed first. Secondly, the actual task of the clinical psychologist to a skin department will be dealt with. Thirdly, some scientific methods suitable for such work will be examined.

RELATION BETWEEN DERMATOLOGIST AND PSYCHOLOGIST

First, psychology and dermatology must be considered to be on equal footing. Both sides must acquire a true conviction that psychology is a scientific discipline. We say "a true conviction" advisedly. There is a deep-seated tendency to consider the tangible and visible as more apparent, and hence more true, than the intangible, which is often considered for this very reason to be obscure. A further reason is that psychology is still widely denied the status of a science, and the misuse of psychology and the disregard of its potentially scientific value by dermatologists and psychologists alike is calculated to perpetuate this attitude. It cannot be too strongly emphasised that psychology should not be looked upon as a common-sense adjuvant to dermatologists, but rather as a scientific instrument in dermatological research. If psychology is relegated to the position of "yet another test," no deeper understanding of a truly psychosomatic connection can ever be reached. On the other hand it is important, not only that psychiatrists should apply basic scientific principles in the evaluation of their work, but that, particularly in dermatology, their investigations should be linked with physiological research.

A deprecatory attitude to psychology is apt to have serious consequences. The psychologist is likely to be consulted as a last resort when no physical treatment has proved to be of avail. He will thus see only specially selected cases which tend to blur his view, and lead to lopsided conclusions. The disease mechanisms he is trying to isolate will be obscured by superimposed habit formations accumulated during the long period which has elapsed since the onset of the disease. This is the more unnecessary since an early psychological diagnosis can be made by a well trained psychologist or psychiatrist in much the same way as a dermatological diagnosis. Quite often this can be done in a short interview, the margin of error in a psychological diagnosis being not necessarily any greater than that in medicine generally. We have found that if the psychiatrist attends the outpatient department, and if necessary adds a few casual questions to those of the dermatologist, it is often possible to obtain essential information while the patient—not realising that this is also a psychological interview—has not yet mobilised his conscious or unconscious defences.

If a competitive spirit is allowed to enter into, or even replace, the coöperation between dermatologist and psychologist, it usually ends in each specialist claiming that any benefit to the patient is due solely to his particular treatment. The value of a psychological approach will then be measured by the results of treatment. Actually the evaluation of therapeutic results is a formidable scientific task and in every branch of medicine has to be approached with extreme caution. In dermatology it is particularly unwise—however tempting—to draw definite conclusions about the cause of the disease from the results of either physical or psychological treatment, whether they be positive or negative. It is extremely doubtful whether satisfactory results of treatment will reveal the cause of the eruption: first, because psychological factors enter into every physical treatment to some extent (whether recognised as such or not), or in other words the doctor-patient relationship may far outweigh the benefit of a prescribed ointment; secondly, during psychological investigation or treatment an eruption of cutaneous origin may undergo spontaneous involution because of unrecognised somatic influences. Alternatively, psychological tensions other than those directly responsible for a skin symptom may have been lessened by psychotherapy, so that the total strain on the personality may have been eased and the stress which had found expression in the symptom can now be borne without leading to somatic disturbance.

Similarly, negative therapeutic results cannot be taken to exclude either physical or psychological causation. It is a truism to say that physical illness refractory to physical treatment is yet a physical illness. Similarly, if a psychotic proves inaccessible to psychological treatment, one does not conclude that his condition is not psychological. In skin patients in particular, there is often a nice balance of somatic and psychological factors; a change in either of them may tip the balance towards symptom resolution. It is not of course intended to suggest that results of treatment cannot be taken into account at all when assessing the cause of a disease. But a premature *post hoc propter hoc* must studiously be avoided.

PLACE OF THE PSYCHOLOGIST IN DERMATOLOGY

The psychologist invading a skin department has a double function: first, with the means at his disposal to help as many patients as possible in as short a time as possible; secondly, to make investigations exact enough to merit the name of "scientific research." These two tasks are not identical.

By its nature, short psychotherapy is a hit-or-miss method. But these short cases, too, could be exploited in the interest of deeper understanding. It is not enough to be content with positive results. It is necessary to assess the various mechanisms which are operative in the treatment, and to distinguish in psychological terms what has brought about the improvement. There are a variety of curative factors at work in short psychotherapy; for example, reassurance, catharsis, "confession," the alleviation of anxiety or guilt, or ordinary suggestive influence (intentional or unintentional). The time factor, or the duration of treatment, must also be taken into account. This is particularly true in psychotherapy of long duration, as for instance in psychoanalysis proper, or in group therapy, which may last 12–18 months, sometimes much longer. It may be argued that a given skin disease has a tendency to burn

Medico-Legal Society

The annual dinner of this society is being held at the Savoy Hotel, London, W C 2, on Thursday, Jan 11, at 7 45 P M Further particulars may be had from the hon secretary, 40, Carey Street, W C 2

Chemotherapy of Tuberculosis

The Medical Research Council of Ireland is holding a colloquium on this subject in Dublin from July 10 to 13 The speakers will include Dr Marc Daniels and Dr P D'Arcy Hart (London), Prof G Domagk (Wuppertal Elberfeld), Dr W H Feldman (Mayo Foundation), and Dr Edgar Lederer (Paris) Further particulars will be found in our advertisement columns

Compensation for Practices

Doctors in Northern Ireland who wish to claim compensation for their practices and who have not yet received a claim form should apply to the Ministry of Health and Local Government, Stormont, Belfast, or to the Northern Ireland General Health Services Board 27, Adelaide Street, Belfast Details of those who are eligible and further particulars will be found in our advertisement columns

Prescription of Spectacles

Under the National Health Service (Supplementary Ophthalmic Services) Amendment (no 2) Regulations, 1950, the Minister of Health has laid down that, from Feb 1, where an ophthalmic practitioner or ophthalmic optician has caused an excessive cost to the service by prescribing lenses or glasses beyond those necessarily required by the patient, the Minister may, after investigation, direct that a sum be deducted from the remuneration of the practitioner or optician

CORRIGENDUM *Primary Streptomycin resistant Tuberculosis* —In fig 4 of the paper by Dr Tinne and Dr Henderson (Dec 30, p 901) the resistant strain is above the control

ASSOCIATE CHIEF ASSISTANT IN THE DEPARTMENT

Six years ago one of us wrote a paper intended to focus attention on psychological factors in dermatology (MacKenna 1944). We now try to specify more precisely the psychological factors involved in the production and cure of skin diseases.

Ideally, this psychological and dermatological approach to skin disease should be a double approach made by a single clinician. For reasons of training this is hardly ever possible. Hence it is necessary to establish fruitful coöperation between the dermatologist and the clinical psychologist. This may seem a banal statement, but in reality there might easily enter into such common work a sense of rivalry concerning the scientific priority and validity of the two disciplines. Since some of the differences between the two approaches are fundamental, they will be discussed first. Secondly, the actual task of the clinical psychologist to a skin department will be dealt with. Thirdly, some scientific methods suitable for such work will be examined.

RELATION BETWEEN DERMATOLOGIST AND PSYCHOLOGIST

First, psychology and dermatology must be considered to be on equal footing. Both sides must acquire a true conviction that psychology is a scientific discipline. We say "a true conviction" advisedly. There is a deep seated tendency to consider the tangible and visible as more apparent, and hence more true, than the intangible, which is often considered for this very reason to be obscure. A further reason is that psychology is still widely denied the status of a science, and the misuse of psychology and the disregard of its potentially scientific value by dermatologists and psychologists alike is calculated to perpetuate this attitude. It cannot be too strongly emphasised that psychology should not be looked upon as a common sense adjuvant to dermatologists, but rather as a scientific instrument in dermatological research. If psychology is relegated to the position of "yet another test," no deeper understanding of a truly psychosomatic connection can ever be reached. On the other hand it is important, not only that psychiatrists should apply basic scientific principles in the evaluation of their work, but that, particularly in dermatology, their investigations should be linked with physiological research.

A deprecatory attitude to psychology is apt to have serious consequences. The psychologist is likely to be consulted as a last resort when no physical treatment has proved to be of avail. He will thus see only specially selected cases which tend to blur his view, and lead to lopsided conclusions. The disease mechanisms he is trying to isolate will be obscured by superimposed habit formations accumulated during the long period which has elapsed since the onset of the disease. This is the more unnecessary since an early psychological diagnosis can be made by a well trained psychologist or psychiatrist in much the same way as a dermatological diagnosis. Quite often this can be done in a short interview, the margin of error in a psychological diagnosis being not necessarily any greater than that in medicine generally. We have found that if the psychiatrist attends the outpatient department, and if necessary adds a few casual questions to those of the dermatologist, it is often possible to obtain essential information while the patient—not realising that this is also a psychological interview—has not yet mobilised his conscious or unconscious defences.

If a competitive spirit is allowed to enter into, or even replace, the coöperation between dermatologist and psychologist, it usually ends in each specialist claiming that any benefit to the patient is due solely to his particular treatment. The value of a psychological approach will then be measured by the results of treatment. Actually the evaluation of therapeutic results is a formidable scientific task, and in every branch of medicine has to be approached with extreme caution. In dermatology it is particularly unwise—however tempting—to draw definite conclusions about the cause of the disease from the results of either physical or psychological treatment, whether they be positive or negative. It is extremely doubtful whether satisfactory results of treatment will reveal the cause of the eruption: first, because psychological factors enter into every physical treatment to some extent (whether recognised as such or not), or in other words the doctor-patient relationship may far outweigh the benefit of a prescribed ointment; secondly, during psychological investigation or treatment an eruption of cutaneous origin may undergo spontaneous involution because of unrecognised somatic influences. Alternatively, psychological tensions other than those directly responsible for a skin symptom may have been lessened by psychotherapy, so that the total strain on the personality may have been eased and the stress which had found expression in the symptom can now be borne without leading to somatic disturbance.

Similarly, negative therapeutic results cannot be taken to exclude either physical or psychological causation. It is a truism to say that physical illness refractory to physical treatment is yet a physical illness. Similarly, if a psychotic proves inaccessible to psychological treatment, one does not conclude that his condition is not psychological. In skin patients in particular, there is often a nice balance of somatic and psychological factors; a change in either of them may tip the balance towards symptom resolution. It is not of course intended to suggest that results of treatment cannot be taken into account at all when assessing the cause of a disease. But a premature *post hoc propter hoc* must studiously be avoided.

PLACE OF THE PSYCHOLOGIST IN DERMATOLOGY

The psychologist invading a skin department has a double function: first, with the means at his disposal to help as many patients as possible in as short a time as possible; secondly, to make investigations exact enough to merit the name of "scientific research." These two tasks are not identical.

By its nature, short psychotherapy is a hit-or-miss method. But these short cases, too, could be exploited in the interest of deeper understanding. It is not enough to be content with positive results. It is necessary to assess the various mechanisms which are operative in the treatment, and to distinguish in psychological terms what has brought about the improvement. There are a variety of curative factors at work in short psychotherapy; for example, reassurance, catharsis, "confession," the alleviation of anxiety or guilt, or ordinary suggestive influence (intentional or unintentional). The time factor, or the duration of treatment, must also be taken into account. This is particularly true in psychotherapy of long duration, as for instance in psychoanalysis proper, or in group therapy, which may last 12–18 months, sometimes much longer. It may be argued that a given skin disease has a tendency to burn

Medico-Legal Society

The annual dinner of this society is being held at the Savoy Hotel, London, W C 2 on Thursday, Jan 11, at 7 45 P M Further particulars may be had from the hon secretary, 40 Carey Street, W C 2

Chemotherapy of Tuberculosis

The Medical Research Council of Ireland is holding a colloquium on this subject in Dublin from July 10 to 13 The speakers will include Dr Marc Daniels and Dr P D'Arcy Hart (London), Prof G Domagk (Wuppertal Elberfeld), Dr W H Feldman (Mayo Foundation), and Dr Edgar Lederer (Paris) Further particulars will be found in our advertisement columns

Compensation for Practices

Doctors in Northern Ireland who wish to claim compensation for their practices and who have not yet received a claim form should apply to the Ministry of Health and Local Government Stormont, Belfast, or to the Northern Ireland General Health Services Board, 27, Adelaide Street, Belfast. Details of those who are eligible and further particulars will be found in our advertisement columns

Prescription of Spectacles

Under the National Health Service (Supplementary Ophthalmic Services) Amendment (no 2) Regulations, 1950, the Minister of Health has laid down that, from Feb 1, where an ophthalmic practitioner or ophthalmic optician has caused an excessive cost to the service by prescribing lenses or glasses beyond those necessarily required by the patient, the Minister may, after investigation, direct that a sum be deducted from the remuneration of the practitioner or optician

ppearance or formation of a symptom owes its existence the first place always to what is called the primary ain Primary gain is an attempt of the mental apparatus nder stress to secure or make possible the continued xistence of the personality as a whole Secondary gain of a minor order compared with primary gain, though one the less welcome when procurable The social ain in psychosomatic disease, in contradistinction to ysteria, can be expected to have much less importance, ven to be absent

If psychology is to make any fundamental contribution o dermatology it is essential to establish a clear differential diagnosis between a psychoneurotic and a psycho omatic manifestation Psychoneurotic symptoms occur when repression is faulty—i e, when repressed unconcious conflicts force a way through mental defences To apply the psycho analytic structure of the psychoneuroses to all skin manifestations will prove a stumbling lock to research into skin conditions It is at the same ime a doubtful service to psycho-analysis itself Somatic nanifestations are more primitive, and their mechanism s simpler, than the elaborate mechanism of the psycho neuroses Somatic manifestations such as skin disease are mostly "affect equivalents"—they may be a disguised discharge of anxiety, fear, rage, or any other simple affect They are due to a lack of discharge through conscious channels or to over-excitation and hence damming up It is well to admit, even to stress, that the detailed mechanism of such affect equivalents is not fully understood, and that much work will have to be done to explain in detail such "somatic behaviour" Research on these lines must include a study of emotional expressions and their disturbances, both from the psychological and physiological angle The following is an example of a simple affect equivalent

A woman of 45 had been suffering for 3 months from blepharitis, conjunctivitis and itching round the eyes She was for all practical purposes a well-adjusted woman—a wife a mother of two grown up children and doing a part-time clerical job She could not account for her symptoms, but on questioning it appeared that the trouble had started gradually about three weeks after the loss of her father, to whom she the eldest daughter, had been very much attached. Asked what the loss of her father meant to her she said that it had been a very great blow, and she volunteered the information that she had not shown much sorrow at the time of his death because she wanted to spare her mother s feelings She added that her own family had been surprised to find her so composed. Being given the opportunity "to let go during two therapeutic sessions her eye symptoms cleared up

The mechanism of the itching and inflammation round the patient's eyes may be looked upon as a "retention formation" in so far as an emotional response which had been denied an outlet at the proper time was later discharged in a less intense but more protracted and disguised form

Psycho analysis is the only method in which investigation and treatment coincide. The classical method cannot, for obvious reasons of time, be carried out in an outpatient department, but something approaching the classical method may be attempted in special cases What is often described as "short psycho analytic therapy" is fundamentally different (Macalpine 1950) Any therapy directed against a symptom is basically different from the classical method, in which the personality is allowed to unfold without any interference by the therapist or concentration on the symptom Not even in classical psycho analysis are all the therapeutic agents established beyond doubt It has to be admitted, therefore, that our methods of treatment need clarification, and their rationale more exact formulation

The type of treatment will eventually depend on forming an exact diagnosis if a symptom is psychoneurotic the classical method of psycho analysis is the ideal form of treatment, if however a psychosomatic symptom is—as we believe—of a different order, then other types of treatment are indicated

METHOD

Once sufficient knowledge has been assembled about the psychological aspect of a certain skin disease it may be possible to proceed to generalisations and eventually to establish certain reaction types, but it seems timely to warn against a too ready correlation of diseases with personality types In the literature skin patients are often referred to as "obsessionals" without any indication as to whether this is to be understood as a patient suffering from an obsessional neurosis or whether it is meant to describe with a convenient label a character make up within the normal range Even if it is ascertained that a person suffers from an obsessional neurosis, his skin symptom may yet be—and often is—a hysterical formation, or it may be superimposed and of different origin, and of an independent mechanism A depressed person may be easy to recognise, but from the standpoint of psychodynamics various forms of depression can be differentiated, reflecting disturbances at different levels, and having an entirely distinct significance If a skin patient is depressed the important question is whether the skin condition is a sequel to, the cause of, or coexistent with the depression Needless to say the patient's opinion cannot be taken as valid. Most skin patients insist that their depression is the consequence of an irritating, incapacitating, or disfiguring skin complaint But their depression often persists after the skin has cleared up

These considerations indicate that much must be done before we can hope to associate certain skin diseases with definite psychological constellations The urge to fasten certain skin diseases on to certain types is fraught with all the dangers of scientific short-cuts

Papers have been published in which, for instance, eczema is said to be due to aggressiveness or aggression This implies that one particular drive is considered the causative factor in the production of a skin disease But the aggressive drive is not only normal but a prerequisite of a normal personality, and it follows that no illness can be traced to it It is sometimes stated that a patient's aggression has reached abnormal heights To take an analogy from the physical side, this equals the statement that certain skin eruptions are due to, say, histamine Only through recognition of the vicissitudes aggression has undergone in the economic or dynamic household of the mental apparatus can we acquire deeper understanding of the part it plays in the formation of skin symptoms. If it were only a matter of an undue inborn pathological amount of aggression, one would more logically expect such a patient to become a violent criminal than a suffering skin patient If the dynamic principle of the mental apparatus is disregarded, we are thrown back once more into pre Freudian days of rigid syndromes and their description. So whether there is too much or too little aggressiveness (and the too little, although less often emphasised, may be the more serious and ominous of the two), an assessment of the quantitative factor alone will not better our understanding, but will eventually place us in a constitutional impasse It was precisely this constitutional impasse which so dissatisfied Freud that he started to work on dynamic lines In his early days hysteria was regarded as a constitutional degeneration. The pertinent question to be raised is why in any given case is there an insufficient outlet for or sublimation of, or mental defence against, aggression, or again, why has a skin patient so little tolerance to it that a pathological discharge into somatic channels takes place.

To give another illustration, it is often stated that skin patients have increased masochistic tendencies It itself out during such a period, irrespective of any other influence Evaluation of results, if they are to carry conviction, must therefore take this time factor into consideration

Other factors, too, deserve closer study We have found, for instance, that some skin conditions may disappear without any alteration in the personality A patient with pruritus may report as a first sign of improvement that his itch is no longer so severe, that the impulse to scratch is no longer so urgent or compulsive, or that it seems to come more from the surface than from inside the body In other patients, such as those with eczema of long standing, a personality change may be conspicuous before there is any symptomatic improvement Such patients report that their skin lesion is unchanged but that they feel happier in themselves and more capable of satisfactory adjustment, either in their work or in their social contacts The improvement of the skin disease lags behind a general improvement Some patients, on the other hand, relinquish their symptoms dramatically

A woman, aged 30, had suffered for 18 months from severe eczematous lesions, with an excruciating itch of both fore arms, wrists and neck, where she had extensive scratch marks After the third psychological interview—to the surprise of the therapist—she was clear of her eczema and free from itching, with only a few healing scratch marks left She had been violently opposed to psychological treatment

We agree warmly with Stokes and Beerman (1948) that clinical observation during the interview is a valuable aid to psychological diagnosis It can often be found that an itching skin complaint will behave like a sounding board when a certain topic is mentioned

In a woman with acute dermatitis of the whole neck the lesion became purple and started to exude profusely when she related humiliating situations to which she had been exposed, and to which she could not react at the time of their happening She was quite unaware of this " organ language ", in fact she excused herself for rubbing and wiping her neck during the interview by explaining that " for no reason what ever " these bouts of itching and weeping of her neck would suddenly occur

In another case of acute generalised eczema, a woman of 21 started to scratch frantically whenever her relationship to her father was discussed

Thus even from " short-treatment " cases considerable insight can be gained, but deeper understanding can be reached from those patients who can be studied over a long period

As stressed above, results of treatment have unjustifiably been taken as methods of investigation Not only have they been unduly used to explain the cause of a skin disease, but a further error in method has crept into some of these investigations the literature shows that therapists are inclined to conclude that what has cured the patient is the particular brand of psychology in which they themselves are trained and naturally believe These disputes between psychologists of various schools have the more prejudicial effect on psychosomatic research in that they tend to focus attention too exclusively on mental conflicts and their psychic resolution The illness, its symptoms, and its solution or cure are regarded as occurring in the psychological sphere According to this view, a mental conflict can be expressed in words, it has a meaning and it is easily understandable, when somatic disturbances appear they serve to express or dramatise mental conflict For instance, a patient may have a skin rash on his hands, his symptom represents symbolically, in the form of a compromise, a conflict between wishing to do and defending against doing a forbidden deed Such would be the underlying dynamics of the hysterical symptom formation according to Freud As in the case of a phobia, the symptom represents a compromise between two opposing tendencies, and, of course, somatic manifestations such as skin disease may have such a conflict meaning

A man, aged 35, was seen with a circumscribed eczematous lesion without scratch marks over the knuckles of the first and second digits of his hands He described the sensation of this lesion as irritating, not violently nor constantly, but occurring in bouts,-particularly at periods when he was idle. To relieve this itching sensation he said he never scratched violently at any time, but " I put my hands into my trouser pockets so far that the lesion rubs gently against the seam and," he continued, " I have to rub it against something which is soft and firm at the same time " His marital relations had been severely curtailed (coinciding with the lesion on the hand) because of a protracted illness on the part of his wife Owing to a frustration of his hetero sexual life the temptation arose to revert to the forbidden masturbatory practices of adolescence His skin rash represented both a gratification and the defence against it, he was altogether unaware of the symbolism of rubbing against something 'firm and yet soft " The eczema on his hands cleared up completely after six sessions

Such cases follow the classical symptom formation which Freud has described for the psychoneuroses Because the symbolism of such psychoneurotic symptoms can relatively easily be discerned, there is a tendency among workers in this field to read such a *symbolic* content into all skin manifestations This has led many to assume tacitly that all psychosomatic illnesses can somehow or other be considered as psychoneuroses But somatic manifestations are by no means always, or even predominantly, psychoneurotic (Glover 1949) In contradistinction to psychoneurotic symptoms they have no meaning, no psychic content, and their formation does not follow the classical pattern indicated by Freud for the psychoneuroses Indeed, it is well to remember that the incidence of psychosomatic disease is far higher than the incidence of the psychoneuroses

The neglect of purely clinical and physiological data when skin disease is looked upon as of the same order as the psychoneuroses may be illustrated in this way

Some writers describe adult endogenous eczema as being based on certain conflict patterns of an adult preconscious type—for instance, over-dependence/independence Certain types of infantile eczema (of the eczema-asthma-hay-fever type) cannot be accounted for by the same mechanism unless of course the observer assumes that in the case of infantile eczema a mental apparatus of such maturity exists that mental conflicts of an adult preconscious order can occur Yet infantile and adult eczema seem to constitute a nosological entity, and no theory which does not embrace both types can be considered complete or valid The mental complexity of the adult observer may easily mislead him into reading his own complicated mental structure into the simpler mental structure of the infant This tendency has led some psycho-analysts *into assuming adult functioning* in the infantile body/mind unit But this attitude seems to brush aside the basic fact that an immature structure cannot be taken to have adult function Form and function are but two aspects of the same thing, they are intimately linked up together A baby in arms cannot conceivably experience conflicts of the same order as the adult The carrying back of adult conception into the first year of life (as is necessary if adult and infantile eczema are to be correlated on a conflict interpretation) furthermore makes nonsense of dynamic developmental approach in psychology

Moreover, if a skin symptom is always considered to be psychoneurotic, the social gain of such a symptom (i e, the quest for sympathy, commiseration, love, and attention, or the infliction of punishment or revenge on the environment) is often overemphasised by the observer It has even led to skin disease being explained *solely* on the grounds of social gain This " secondary gain " does of course exist, it is, in fact a regular occurrence of some importance in hysteria But even in hysteria the secondary gain is, after all only secondary The

RECENT HISTORY OF CORONARY DISEASE[1]

J N Morris
M A Glasg , M R C P , D P H
From the Social Medicine Research Unit, Medical Research Council

(*Concluded from p 7*)

Questions Arising

The volume of evidence that can be presented from his single study is small in relation to the size of the problem and its complexity And the present findings may be disqualified by the limitations previously mentioned (or by others that have been overlooked entirely) Nevertheless questions must be put about the bearing of these seemingly paradoxical findings on the current picture of the pathogenesis of coronary heart disease, and the suggestion that coronary atheroma has decreased must be explored

NATURAL HISTORY OF CORONARY HEART DISEASE

According to the current view there are, locally, three main interacting elements in ischæmic heart disease (Blumgart 1943, Blumgart et al 1940, Friedberg 1949, Horn and Finkelstein 1940, Leary 1934, Parsons Smith 1950, Saphir et al. 1935, Welch 1920, Winternitz et al. 1933) These are

1 Atheroma, with narrowing of the coronary arteries, vascularisation of the intima, necrosis, and hæmorrhage,
2 Recent and old occlusion of the arteries,
3 The collateral circulation,

and their interaction is modified by conditions affecting the cardiac output and the demands on it

Of these three, occlusion is crucial in determining the transition from the merely pathological to the clinical, for the production of the heart disease here considered The occlusion, in turn, whether or not it can result from sclerotic narrowing alone (and this may have been absolutely commoner and relatively more important forty years ago), is due more often to coronary thrombosis, variously produced , and the first line of speculation must be based on the proposition that the central cause of ischæmic heart disease and of its increase lies in coronary thrombosis and the occlusion it causes

The thrombosis and the atheroma are obviously related and are usually regarded as the " acute " and " chronic " phases of one " disease "—whence the notion (if only implicit) of " arteriosclerotic " heart disease The atheroma is the basis of the clotting, which is a complication of the degeneration in the vessel , the more the atheroma the greater is the likelihood of thrombosis and occlusion , and the heart disease is thus the inevitable end result of the advancing degeneration The present observations, however, raise the question whether this notion is any longer particularly useful If there has been an increase in the heart disease, if the atheroma of the victims of the heart-disease is not qualitatively different from the atheroma of the rest of the population, and if the trends shown in tables II and III are generally confirmed—even if only to the extent of showing that there has been no increase of atheroma—then the notion of arteriosclerotic heart disease would be of historical interest only The character of the disease has changed, it seems , the two phases have become dissociated Indeed, with fewer eligible for the heart-disease—*i e* , fewer with advanced atheroma—more seem to suffer from it This would be a general proposition Even if the dissociation has occurred in not more than one population (which has nevertheless shared in the general increase of the heart disease), it must still be considered whether the notion was not too simple in the first place Finally, there are many who remain unconvinced that there has been any increase of ischæmic heart disease during this century But there is no suggestion that it is in fact becoming more rare On this basis alone the possibility of a decrease in coronary atheroma must raise questions on the meaningfulness of many of today's assumptions about the pathogenesis of the heart disease More cogent reasons for doubt than anything said here are provided by the common observations that only a fraction of those with severe coronary atheroma have the heart disease (Blumgart 1943, White et al 1950, Wyn Jones 1931), and that those who do have the heart disease may have only moderately severe atheroma (not to mention the unfortunates with a solitary plaque), whereas many with very severe degeneration escape Explanation of such phenomena in terms of a particularly effective anastomotic circulation may partly be begging the question, because it may only be with repeated occlusion that the question commonly arises Moreover the thrombosis and the heart disease seem to be increasing as much at earlier ages as in later life, when there is manifestly more degeneration, and perhaps more in the middle aged than in the very old

What then is the relation of coronary thrombosis and heart disease to coronary atheroma ? Perhaps advanced atheroma provides the basis, is the predisposing factor , but what will precipitate the heart disease, who of the many so predisposed will develop the thrombosis/occlusion, and when, may not be a function simply and directly of the atheroma or of its severity There may be a necessary and critical level of atheroma (Leary 1934, Saphir et al 1935) that is the *condition* of the heart-disease , but beyond that other factors are possibly more important as *causes* of it The indication may therefore be to pay less attention to the atheroma which predisposes, and more to the thrombosis which precipitates, the heart disease

There are two main aspects of this thrombosis the coagulating blood and the local disturbances of the degenerate vessel that provide the setting and opportunity for the clotting Fundamental questions of constitution and personality, nutrition, hæmodynamics, and endocrine responses are involved in these processes, and more specific ones Is there any evidence, for instance, of changing frequency in intravascular thrombosis at other sites ? Pulmonary embolism might be so investigated, though this would be very difficult (Strom 1950) Are sufferers from coronary thrombosis prone to clotting elsewhere ? (Meakins and Eakin 1932) How are intimal necrosis or mural hæmorrhage, the rupture of atheromatous " abscesses," or the separation of plaques related to changes of heart beat and blood pressure, to dilatation and spasm of the coronary arteries ? (Blumgart 1943, East and Oram 1948, Friedberg 1949, Horn and Finkelstein 1940, Master et al 1939, Paterson 1938, Winternitz et al 1933) And what of the relations of habits of life and psychological forces to the neural and humoral mechanisms of these ? (Bülbring et al 1949, Proceedings of the First National Conference on Cardiovascular Disease 1950, *Psychosomatic Medicine 1945*, Registrar General's Occupational Mortality Supplement 1938, Wolff 1950)

As yet there is little warrant for this shift of interest from the chronic events of coronary heart disease to the acute, either in the clinical history of victims (where the frequency of silent thrombosis and infarction is only one of the difficulties) or in studies of their blood coagulation (Boyer 1946, Friedberg 1949, Mintz and Katz 1947, will be realised that the skin is the predominant seat of masochism, hence this statement gets no further than its starting point, and leads to a stalemate It is again only the study of the underlying dynamics which will yield an answer to the question why does one patient show more masochism than another ? It is in any case necessary to distinguish between primary (mostly constitutional) and secondary (developmental) masochism It is undisputed that women have by nature stronger masochistic (passive) tendencies than men , and one might accordingly expect to find that severely itching forms of endogenous dermatoses would be more prevalent among the female than the male population Common experience suggests, however, that there is no great preponderance of female cases This seems to point to the fact that primary masochism is not responsible for the formation of the skin complaint , hence it is doubly necessary to differentiate between primary and secondary masochism Secondary masochism comes into operation when aggression can no longer be turned outward, either against people or in a sublimated form to attack tasks and problems of daily life One has to find the cause for this incapacity to show or tolerate aggression and to the subsequent " turning in on the self " of aggressive drives Many factors may make the normal display of aggression impossible for a person—among them guilt feelings, anxiety, or fear of injuring or destroying a love object

---

[1] " Coronary disease " is taken here to include (1) coronary atheroma (atherosclerosis) and (2) coronary, ischæmic (arteriosclerotic) heart-disease, particularly the syndrome of thrombosis, occlusion, and infarction and its variants " Ischæmic ' heart-disease is the most accurate term, but " coronary " heart-disease is convenient and in too common use to be discarded

Another example of the pitfalls of neglecting the dynamic approach can be found in the evaluation of " precipitating factors " These are often considered to be obvious inasmuch as they have a certain reality value But this view is highly misleading The precipitating cause of a skin disease is only very exceptionally known to the patient, and even if it is known its unconscious meaning is not understood Quite commonly the patient will present the psychologist with what one might term a " cover cause "

A woman of 48 suffered from intermittent attacks of urticaria She related that she had noticed her outbreaks occurring after eating fish on Fridays She had lost her only son during the late war and was preoccupied with guilt feelings towards him She had wanted to give him a good education and had saved up to give it him on his return When these problems were worked through with her, the outbreaks of urticaria stopped Her son had been killed on a Friday

The reality value of these precipitating factors is much smaller than is usually assumed The great adversities of life—as for instance the loss of dear ones—are astonishingly rarely followed by the outbreak of a skin disease Further, reference is often made to precipitating factors without due regard to the period intervening between the impact of these and the onset of the disease This period might be compared to the incubation period of infectious diseases and certainly merits closer attention not only as to duration but also to inter current developments in the psychic apparatus—a point which had already been noticed by Freud in 1895 The term " trigger reaction " which has found its way into psychological writings must be viewed with some suspicion Trigger reactions are not standard behaviour patterns of fixed value The psychologist is concerned rather with the cartridge which the trigger fires he must discover how it got there and how it is that certain psychic constellations act as an explosive agent

CONCLUSIONS

The psychologist approaching skin disease should have an open mind with as little bias as possible in regard to method A sound training both in psychology and psychiatry is necessary The clinical psychologist should keep in touch with the clinical and physiological aspects of his work Both aspects of the problem should constantly be correlated

We would like to single out at random three problems where such correlation of approach is likely to be fruitful The first is an attempt to evaluate the factors that determine whether a skin disease will take an acute subacute, chronic, recurrent, or intermittent course. The second concerns abnormal skin sensibility the hyperæsthesia and hyperalgesia which may be demonstrated by a physiologist who investigates many itching skin diseases seems to us closely related to the increased skin libidinisation of the psycho analyst Thirdly, the phenomenon of itching with its attendant rubbing and scratching seems to present a vast field for investigation from both the physiological and psychological angle. Itching, although one of the commonest symptoms, has not as yet received the detailed and all round investigation it deserves

Reviewing some of the present trends in psychological investigation of skin disease, we have pointed out blind alleys, and errors and pitfalls in method , for it is often an advance in research to do no more than to specify problems more accurately and to re examine fundamental issues

Attention has been drawn to the common mistake of classifying certain skin patients as psychoneurotics. Whereas the structure and the dynamics of the psycho neuroses are well established, in Freudian theory, the separate mechanisms governing psychosomatic behaviour have yet to be worked out Freud (1929) himself insisted that psycho analysis which had uncovered the structure of the psychoneuroses (the " transference neuroses" proper) " had but little to add to the clarification of the common neuroses (the " actual neuroses "), this task, he maintained, had to be left to biological and medical research

It has been suggested that a study of emotional expression both physiologically and pathologically is essential to accurate understanding Such an approach would not only correlate physiological with psychological data, but would conceivably throw light on some pathological aspects of the dermatoses As Erasmus Wilson said as long ago as 1870 " The limits between the physiological and pathological are barely discernable The blush of emotion is scarcely to be distinguished from the blush of transient erythema or urticaria, and the too frequent repetition and the permanence of the blush become a confirmed erythema, as in gutta rosea" (rosacea)

As some of the opinions submitted in this paper may not be accepted by all psycho analysts, or for that matter by all non analytical students in this field, we wish to state that we have expressed only our personal views

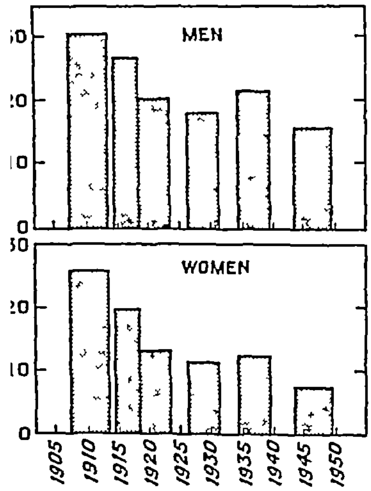
' So long as a variety of hospitals remained under the direct control of the department, a great deal could be done to assist families by arranging for the removal to hospital of patients suffering from various sorts of illness, but especially of patients suffering from chronic sickness and even of old people who were feeble enough to require treatment as patients it would be of great help to the department and to the people if it had control of the use of at least a certain number of beds, and was thereby able promptly to admit a patient after consideration of the medical certificate and of the social conditions of that patient in relation to those of others recommended for admission —Dr W L BURGESS, M O H for Dundee in his report for 1949



4—Prevalence of advanced coronary heroma at the age of 50–70 in men and in omen (data from necropsies at the London ospital) each hatched column shows erage percentage for the years included, d the percentages are standardised on e age-distribution of the population of ngland and Wales in 1947

iring forty years is associated with nutrition, with ianges in the national diet A clue to the answer may provided by a more detailed study of the behaviour of atheroma in this London Hospital series The condition of the coronary arteries in 1915–39 was therefore investigated with the material and methods already described The 1915–18 to 1927–31 figures include all the available reports, those for 1935–39 include only the reports of Dr Woods and Professor Russell, so as to permit more direct comparison with the figures given previously for 1944–49 Fig 4, which ates the data of tables IV and V to those of les II and III, shows the same broad tendency in th sexes, and it may be summarised as follows decrease between 1908–13 and 1919–23, then small anges till 1935–39, and a further decrease in 1944–49 is interesting that decreases occurred during both ioning periods (Aschoff 1924, Beveridge 1928, Ministry Food 1949, Vartiainen and Kanerva 1947), and this cords with many views on intake of animal fat, the ood lipids, and atheroma The nutritional relations of heroma are now being unravelled, and not only is ere promise, with the application of physical chemistry well as biochemistry, that the rôle of the lipids, cluding cholesterol, will be clarified, but it may soon so become possible to consider other possible connec ons between atheroma and diet Questions already ise about the extraction rate of flour, the vitamin B mplex, and intermediate cholesterol metabolism, out choline, other lipotropic factors, and the fatty position, and about the intake of antithyroid sub ances (*Annals of Internal Medicine* 1950, Cowdry 1933, Ministry of Food 1949, Gofman et al 1950, Hueper 1944–45, 1949, Steiner 1950) The calcification, as distinct from the fatty stage, might have been mainly decreased —which recalls one feature of the nutritional history of the first world war (Drummond and Wilbraham 1939) Other changes, however, should also be remembered, there was, for instance, a steep decline in the consumption of alcohol during the first war, and there may have been something of this among civilians in the second More over, it is no longer altogether fanciful to think of diet in relation to hypertension Such a coincidence of decrease in atheroma with food rationing suggests that the present findings are not due to special causes operating locally in this particular population, but may be of more general significance There is insufficient evidence on which to discuss other possible factors in the decrease, such as changes in the water supply and cooking habits

BLE IV—PREVALENCE OF ADVANCED CORONARY ATHEROMA MALES AGED 50–70 AT NECROPSIES IN THE LONDON HOSPITAL

Age group (yr)	No of cases							
	In 1915–18		In 1919–23		In 1927–31		In 1935–39	
	Total	Proportion with advanced atheroma	Total	Proportion with advanced atheroma	Total	Proportion with advanced atheroma	Total	Proportion with advanced atheroma
0–54	123	12 %	139	14 %	169	8 %	62	13 %
5–59	107	24 %	140	18 %	183	16 %	84	17 %
0–64	94	30 %	109	21 %	143	17 %	62	26 %
5–69	62	50 %	63	33 %	89	38 %	54	37 %
Total	386	St rate 50–69 27 0 %	451	St rate 50–69 20 4 %	584	St. rate 50–69 18 2 %	262	St rate 50–69 21 7 %

These cases form group C Deaths from coronary heart disease, om hypertensive disease from arteriosclerosis in other sites and ith diabetes are not included.

St rate = standardised rate

As interesting as these reductions is the modest recovery during the inter war period which left the level at its close (1935–39) about the same as at its beginning (1919–23) This was not the case with diabetes and gall bladder mortality—also possibly related to fat intake—which fell in both wars and rose between them Perhaps such increase in fat consumption as occurred in this section of the population during the inter war years was adequately covered, vis à vis atheroma, by other simultaneous improvements in the diet, but there is no basis for such speculation Possibly the suggestion of an increase in coronary atheroma in the relatively prosperous years of 1935–39 may be significant Possibly there is here a combination of "generation" and contemporaneous effects on the cohort exposed during the first world war Possibly the small response during 1919–39 merely reflects technical flaws and inadequacies of the present approach to the problem

TABLE V—PREVALENCE OF ADVANCED CORONARY ATHEROMA IN FEMALES AGED 50–70 AT NECROPSIES IN THE LONDON HOSPITAL

Age group (yr)	No of cases							
	In 1915–18		In 1919–23		In 1927–31		In 1935–39

See footnote to table IV

I do not feel competent to discuss the relevance of these findings to the various theories of the pathogenesis of atheroma other than nutritional (Duguid 1949, White and Ferrero 1949) Nor can the relevance of animal experimentation on atheroma to the human problem be considered here I have dealt only with the coronary arteries, but may be able to report later on the abdominal aorta The question of the special localisation of atheroma would be most usefully discussed in the present connection, when comparative evidence on the historical trends of atheroma in different arteries is available

Indicator of Atheroma Further Validation

Tables IV and V again show fairly regular patterns with age and sex. An attempt was now also made to compare in finer detail the findings for 1935–39 with those for 1944–49, as the reports of Dr Woods and Professor Russell alone were analysed for these years In this period the reduction in

Peters et al 1946), though emphasis on the thrombosis has in a different way improved the possibilities of treatment

Decrease of Atheroma and Increase of Heart disease

Another question must be put Is the decrease of atheroma suggested by tables II and III unrelated to the increase of heart disease shown by table I, having merely coincided in time, or are the two processes in some part cause and effect ? How sensible this question is depends primarily on whether the decrease is general, granted that the increase has been observed in many populations Two obvious mechanisms whereby a decrease of atheroma might so operate suggest themselves If calcification is a method of healing of atheromatous lesions, and during the process mural capillaries are obstructed (Winternitz et al 1933) and atrophy, a decrease in calcification may favour an increase of subintimal hæmorrhage (Buck et al 1950, Cowdry 1933) Spasmodic contraction, too, may be commoner in vessels not so calcareous More generally, a decrease of the atheroma might promote the development of the heart disease because with less narrowing of the arteries there may be less stimulation to open up the intercoronary vessels This might be of particular moment if acute thrombotic occlusive lesions were increasing for other reasons, and if emergency responses of the anastomotic circulation were not fully effective But these are not problems that can be investigated from the present material Nor is it possible to do more than put the cognate question—whether ischæmic heart disease is occurring more commonly in persons with less severe atheroma, whether (as it were) there has been a lowering of the critical level of coronary atheroma This last proposition would, of course, go further than that previously put forward, which merely suggested that the heart disease is increasing despite the decrease of severe atheroma—without implication about the degree of atheroma necessary in the individual case The nature of the present material cannot permit of an estimate even of the amount of calcification in the coronary arteries of those dying from coronary heart disease

Increase in Heart-disease, and its Prevention

If the present observations are sound, explanation of the increase of coronary heart disease by an increase of the predisposing atheroma becomes unconvincing The mechanism of the increase may be an increase of the thrombosis that is the precipitating cause, and—possibly serious in relation to the collateral circulation—this may be occurring at younger ages than formerly In turn this increase in thrombotic accidents or incidents may be due to changes in the coagulability of the blood or to an increase of disorders in the vessel wall that promote coagulation No clue to the causes of the increase of the heart disease has emerged, except for the suggestion of a qualitative change in its incidence about the close of the first world war This, if confirmed, would indicate study of changing modes of life and the changing environment, the epidemic constitution, of those years

Two possible approaches are indicated to the prevention of coronary heart disease Control may be achieved through reduction of the predisposing atheroma But if the heart disease is increasing because the precipitating thrombosis is increasing, the reduction might have to be very radical to show results The indications are that even now only a small minority of those "eligible" in terms of coronary atheroma do actually have the heart disease, at any rate in the ages considered If there has been anything like the decrease of advanced atheroma shown by tables II and III, and nevertheless the net result has been the recent increase of the heart disease, it would obviously need a tremendous further decrease of atheroma to annul the effects of the increase in thrombosis—indeed the decrease would have to be as steep as the increase Alternatively, prevention may become possible through control of the intravascular thrombosis A fortiori, these considerations would apply in populations where coronary atheroma has not decreased and there are greater numbers eligible, unless it can be shown that there is an aggravating factor associated with the decrease itself In that event the problem would become even greater—so to control the atheroma that the lesions did not sufficiently mature to form the basis of thrombosis and not only to reduce the volume of severe atheroma

Occlusion without Thrombosis

This "thinking aloud" started from the proposition that coronary thrombosis is the central problem But what of the many cases where no recent thrombus is found ? Should it be a common fact that occlusion can be produced by sclerosis alone, and infarction merely by stenosis, it must make nonsense of much that has just been written If coronary heart disease has increased and the *sufficient cause in a large group* is severe atheroma, the main finding of the present *investigation* becomes suspect on that account alone Theoretically it is possible that the atheroma decreased in the vast majority of the population but increased in a special minority To this it may be objected that severe coronary atheroma, as severe as in these cases *with* the heart disease, occurs so often in those *without* it—an observation that demands a search for additional causes Perhaps some of the explanation lies not in the diseased vessels but in what is required of them

The question arises, however, whether these facts can be accepted They are often not at all clear (and, in passing, one who works much in the "inexact" sciences cannot but be impressed by the differences of opinion among the experts in a field such as this—consider the variation in the reports of mural hæmorrhage alone, for example) Not only may it be very difficult to be sure whether previous thrombosis has participated in an occlusion that appears at present to be merely sclerotic, but it may also be impossible to assess the contribution of old thromboses to the present failure in coronary function Moreover, where arteries appear only to be narrowed, the problem may have to be reconsidered in the light of the work on fibrinolysin and the possibility that thrombus has been dissolved (Macfarlane and Biggs 1949) This aspect of the matter must so unsatisfactorily be left

DECREASE OF CORONARY ATHEROMA

The possibility of a decrease in coronary atheroma between 1908–13 and 1944–49 is interesting from two points of view The first has just been considered—the thinking it may provoke on ischæmic heart disease But the proposition has been advanced that tables II and III are to some extent typical of the general population, or the "hospital class" of it, and the question of a decrease in the atheroma has therefore an intrinsic significance There may be important constitutional elements in coronary atheroma, and there is little doubt that the "population" of 1908–13 was more homogeneous than that of 1944–49, but there is no useful approach along these lines Heredity apart, there are three main sets of conditions associated with the degeneration There is more coronary atheroma among males, and the incidence increases with age, with hypertension (and in hearts of above average weight), with obesity, and in certain metabolic disorders (Friedberg 1949, Wilens 1947) Research today is concerned mainly with the last and, particularly, with the nutritional components The present evidence suggests that there has been a decrease of coronary atheroma in both sexes, at ages 35– or 45–69, in those with and without hypertension The question next arises whether this over all decrease e abdominal aorta, for instance Nor has any attempt ot been made to relate this fundamental pathology of geing to the recent remarkable decline in the death tes of older people (British Medical Association 1950) here seems no reason, perfectionism apart, why it iould not be possible in ten years' time, and again in venty, to provide a comprehensive account of atheroma, oth the degenerative lesions and the occlusive, with iuch finer criteria than was possible in this retrospective udy If a sufficient number of morbid anatomists oöperated, it may be possible to make such judgments y sex and age, by economic status and nature of occupa on, by social and medical history, and even internationally Such an approach is well established in other elds, and valuable knowledge has already been gained om necropsy material about pulmonary tuberculosis nd peptic ulcer Meanwhile the 1944–49 parts of ables II and III provide a limited estimate (because of the estricted sample and the simplicity of the classification) nd a conservative one (because severe hypertension and oronary heart-disease are deficient in the sample) of he prevalence of coronary atheroma in the population oday

Summary

The recent history of coronary disease has been onsidered

Clinical experience and the Registrar General's tables uggest that coronary heart disease has increased, ndependent of the ageing of the population and improved liagnosis

A sample study of coroners' records suggests that spontaneous rupture of a cardiac ventricle in the elderly is similarly occurring more often

An analysis was made of the necropsy records of the London Hospital, where the coronary arteries as well as the myocardium have been routinely examined since 1907–08 Some 6000 reports from these years to 1949 were studied, relating to both sexes and to ages 30/35–69 inclusive

These reports show about a sevenfold increase from 1907–14 to 1944–49 in the number of cases of coronary heart-disease They suggest that coronary thrombosis and myocardial infarction were rare before the first world war and have since become common—i e, that as a common disease they are new and not merely newly recognised The initial and biggest increase in this series took place towards the close of, and in the early years after, the first world war

An attempt was next made to estimate the prevalence of coronary atheroma in the population from these records They showed a substantial decrease of advanced coronary atheroma, as defined mainly by the report of calcified lesions in the arteries, between 1908–13 and 1944–49 The decrease was seen in all the relevant sex, age, and pathological categories (including hypertensive) studied. It occurred in two phases that seemed to be connected with the two world wars

Some implications of these contrasting trends are discussed—e g, that coronary thrombosis and heart-disease may not be simple and direct functions of the atheroma Possible nutritional relations of the decrease of the atheroma are considered, together with their relevance to the health of an ageing population

With new problems of community health, new indicators of what is happening are needed This exercise in documentary research illustrates one kind of contribution that social medicine, on its epidemiological side, may be able to make

I am grateful to many people for their help in the course of this investigation. Prof D S Russell, director of the Bernhard Baron Institute of Pathology granted me free access to the reports and she and Dr W W Woods gave me much valuable advice and criticism. I am also indebted to other members of the staff of the London Hospital, to teachers, friends, and colleagues, and particularly to my statistical colleague, Mr J A Heady, for greatly appreciated suggestions and practical assistance The following kindly gave me information or permission to examine their material Dr E Geiringer, Prof C Polson, Dr C K. Simpson, Dr D Teare, the Registrar General, the Records Officer of the London County Council, and the coroners and their officers for Cardiff, Cardigan District, Devon Barnstaple, Essex North, Gloucester Tewkesbury, Hampshire Fordingbridge Hundred, Leeds, Liverpool, London East and West, Manchester, Middlesex East and West, Oxfordshire West, Salford, Surrey East and West, and Sussex East

calcified lesions, which is primarily indicated by fig 4, may have been accompanied by some reduction in the degree and extent of the fatty lesions "numerous" or "large" or "confluent" fatty lesions were more commonly reported in 1935–39 than in 1944–49, and minor fatty lesions more commonly in 1944–49 than in 1935–39[12] But the categories used are not precise enough to show whether there was a disproportionate decrease of the calcified lesions among all the lesions sufficiently mature to form a potential basis for local thrombosis And, in general, such estimates approximate to the "qualitative" category that has hitherto been avoided in this investigation As regards the main trend of the investigation, the internal consistency of the findings is reassuring in view of the several changes in staff and the gradual amplification of the reports none of the 39 separate sex age groups based on 2535 observations from 1919–23 to 1944–49 exceeded in advanced atheroma the corresponding groups of 1908–13

Recalling the possibility of a "seesaw" effect, it can again readily be shown that improvement in the diagnosis of coronary thrombosis, &c, will not explain away the main trend reported Simple "book keeping," and the addition of all the cases of table I to the figures of tables IV and V, will not make good the substantial and particularly interesting decline of atheroma noticed in 1919–23, for instance But there is a limit to the value of such largely circumstantial evidence, as of the internal consistency of the material, or the logical consistency of the various arguments, and what is needed is further *independent* data

Public-health Aspects

Three plagues seem to have visited the middle aged men of this century peptic ulcer, cancer of the bronchus, and coronary thrombosis There is little as yet to relate them but tobacco, and this is still of doubtful importance in two Coronary thrombosis is the most lethal of the three, and, with hypertension, may possibly be the leading cause of death today The ageing of the community partly explains its greater frequency, but too much is often made of this In the past forty years the numbers eligible by age for angina pectoris, for instance, have little more than doubled Over the same period the number of doctors has increased almost as much Speaking broadly, therefore, each doctor should be seeing on an average about the same number of cases as forty years ago—the problem of recognition apart This is not borne out by general experience Of course it may be that those now living to middle age are qualitatively different, they have survived, or been preserved through, hazards that would previously have been mortal Consequently they may be in some way constitutionally more liable than their coevals of forty years ago to succumb to diseases that are prevalent, including coronary heart disease The fall which is occurring in death rates at all ages might be partly due to the fact that fewer diseases are prevalent As yet there are no satisfactory methods of investigating this kind of problem

A main task of public health is to reduce coronary heart disease and other disorders, and its policies must be based on available knowledge of the causes Today the only hopeful approach to prevention is by controlling the main predisposing condition, coronary atheroma, and this may need to be radical if it is to achieve its object Public health has some experience with this kind of problem, or at any rate with its nutritional aspects There is evidence of geographical, and possibly also of ethnic and class, variations in the incidence of atheroma (Bjornsson 1941, Cowdry 1933, Gordon et al 1939, *Psychosomatic Medicine* 1945, Steiner 1946) I recent years a varied group of nutritional disorders h become less common for various periods—e.g., go cirrhosis of the liver, diabetes, gall bladder dis vesical calculus, chlorosis, and rickets It has beco possible to frame national food policies, though li is yet solved of the problems of health education in subject like obesity At the least, the possibility o such a decrease as fig 4 illustrates, reinforces curre scepticism about the importance of heredity and "bio logical" ageing in determining the severity of atheroma and suggests that there may be an opportunity f rational preventive medicine in this central health problem of an ageing population

Disease, however, is commonly the product of man contributory biological and social factors, as well as o its more immediate conditions and causes, and the factors must also be known This is a main area o epidemiology, the study of disease as a group phenomen in the community, and of its preference for particular ages, occupations, economic classes, and environmental situations Knowledge of such factors may point to more proximate ones, whether predisposing or precipitating, but even basic facts of the prevalence of coronary thrombosis are lacking (Cassidy 1946, Hedley 1939, Johnston 1936, Proceedings of the First National Conference on Cardiovascular Disease 1950, White and Ferrero 1949, Yater et al 1948) Moreover with new health problems now indicators of what is happening in the community are needed The time is probably ripe for the experimental application of the tried techniques of public health to this kind of problem Coronary heart disease could, for example, be "notified" to some public health departments, and, in conjunction with sociomedical surveys, this procedure might be valuable in following up "hunches" about aetiology that are now popular At present the main source of information must be the mortality rates, and cardiovascular disease of middle and old age is, unfortunately one of the darkest areas of vital statistics (The currently certified death rates from hypertension in particular reflect little credit on our medical schools) There is already a case for field inquiry into the meaning and quality of the certification of these conditions, as a preliminary to an educational campaign, though it may be worth waiting to see what new information comes from the introduction of the latest International List It is only possible to speculate now about the significance of the slowing up of the increase in the mortality in England and Wales during the recent war (fig 1), a movement noticed also in Scandinavia and Germany (Lindgren 1950, Strom 1950, Closs and Dedichen 1949) Hospital statistics for this period are more than usually obscure There may well be a clue here to the nutritional relations of coronary thrombosis (and/or hypertension) or to the part played by psychological influences

The present study suggests also that greater use could be made of necropsy material in epidemiological study In the case of coronary heart disease it would be relatively simple to organise some system of ascertainment of spontaneous rupture of a ventricle in the elderly This might be a useful indicator (and it might also have the advantage of bringing forensic medicine closer to the rest of medicine) More obviously, measurements o the prevalence of coronary atheroma in the populatio are needed, and the investigation now reported wa undertaken primarily in an attempt to demonstrat their feasibility At least it has yielded a provocativ picture of changing prevalence over the years It seem a pity that the consequences of the epochal "experimen of opportunity" carried out by war and post war foo policy have not yet been assessed on an adequate scal in terms of arteriosclerosis, of cerebral and coronar atheroma, or, more precisely, as the amount of lipoid i

---

[12] Standardised rates of "early" atheroma at the age of 50–69

	1935–39	*1944–49*
Major fatty lesions		
Male	35 2%	31 0%
Female	25 1%	23 4%
Minor fatty lesions		
Male	40 9%	49 5%
Female	60 8%	65 1%

"Not stated" cases were ignored The few with no coronary atheroma were included in the minor fatty lesions

2 The operation carries a serious risk of injury to the
idder and ureters
3 The whole object of the operation may be nullified by
jury to the peritoneum
4. The operation opens up the extraperitoneal tissues, which
e supposed to have less resistance to infection than the
ritoneum.

ne first two objections have no real substance, since it not intended that the occasional surgeon should tackle ese difficult obstetric problems to the experienced elvic surgeon the operation is one of ease—indeed a urce of pleasure

Any gross invasion of the peritoneal cavity during the peration should be readily avoided, but it must be dmitted that, from time to time, close inspection of the eritoneal flap will reveal minute perforations These ust be closed by simple ligation before opening the terine cavity, so that the full benefits of the procedure y be retained

The last objection must have been raised under a ous misapprehension, the Waters (1940) operation erely involves fascial planes that are of necessity ened up during the course of the commoner transperi neal lower uterine-segment operation and therefore it ould not involve any more risks

TECHNIQUE

Various techniques have been devised Thomas 870), of New York, was the first to perform the opera on, and he recorded (Thomas 1878) 5 cases, with 2 aternal deaths and the loss of 1 fœtus Latzko (1908, 09) devised an improvement that remained the ethod of choice until recently, this gave a rather adequate exposure of the lower uterine segment and as technically difficult if the child was large

A very great advance was made when Waters (1940) nd Ricci (1940) introduced their modification of the d Physick-Sellheim technique Waters's operation ves an excellent exposure of the lower uterine segment, ut his method of dissecting the fascial peritoneal flap om the superior bladder wall can prove both difficult nd tedious By modifying the Latzko operation, orton (1946) obtained a better exposure with less risk f injuring the peritoneum Bourgeois and Phaneuf 1949) advise a bilateral paravesical approach to the wer uterine segment, this modification makes it easier nd quicker to dissect up the peritoneo fascial flap from he bladder, while retaining the advantage of the wide xposure of the lower uterine segment provided by the aters method

We now use the technique of Bourgeois and Phaneuf o attempt will be made to detail the method, but xperience has warned us of certain dangers and difficulties that may be readily avoided Brief mention of hese points may help others to avoid the errors we made

In opening the abdomen great care must be exercised, or it is very easy to open the peritoneal cavity inadvertently, particularly at the upper end of the incision The nterior rectus sheath should be incised at the lower ngle of the wound, and the peritoneum and extraperitoneal fatty tissues should be stripped back with he fingers as the sheath is laid open with scissors The ladder is emptied before the operation, and nothing is gained by filling it with fluid, coloured or otherwise

If the surgeon stands on the patient's right side, a ransverse incision through the transversalis fascia over he bladder is made and extended laterally to the left as the assistant retracts the left rectus abdominis muscle This leads directly to the paravesical triangle, which is bounded above by the peritoneal reflexion, internally by the obliterated hypogastric artery running along the side of the bladder and externally by the left uterine artery The floor of the triangle is covered by the so-called "chicken fat," and, when this is wiped away, the pre-cervical fascia is exposed Division of this fascia allows the bladder to be rapidly mobilised from the uterine wall, and leads on to the dissection of the peritoneo fascial flap from the superior bladder wall. This is easy if the dissection is carried out with a sharp scalpel while the tissues are kept under tension, the urachus will have to be divided between clamps close to the bladder

The peritoneal flap is inspected for perforations at this point in the operation These are readily detected by the leakage of intraperitoneal fluid, and are easily and safely closed by simple ligation (no purse string sutures) The bladder should then be examined and any weak points in its wall oversewn with catgut

At this stage of the operation the freely mobilised bladder is pushed down behind the symphysis pubis out of harm's way, thus exposing the lower uterine segment and cervix in readiness for the usual "trapdoor" uterine incision

The delivery of the fœtal head out of the pelvis may be difficult, but this momentary embarrassment may be obviated by the use of the Trendelenburg position

The uterine incision is sutured in the usual manner with no 5 monofilament 'Nylon,' and the same material is used in closing the abdominal wall The retrovesical area is treated with proflavine (1%) and sulphathiazole (99%) powder, and the space is drained for forty-eight hours

The premedication given to the mother has been atropine gr $^1/_{100}$ Spinal analgesia induced with heavy 'Nupercaine' $^1/_{200}$ in 6% glucose has been the anæsthetic procedure of choice in 47 out of the 52 cases

TYPE OF CASE CHOSEN

The modern operation of lower uterine segment cæsarean section is safe for the mother in cases of election and also when performed early in labour These favourable results are not obtained in the infected or potentially infected patient For this reason Dieckmann (1946) laid down certain criteria by which the dangerous case could be recognised. He advises either vaginal delivery or cæsarean hysterectomy for such patients His contra-indications to transperitoneal cæsarean section are as follows

1 Labour over twenty four hours
2 Membranes ruptured over twenty four hours
3 Attempts at delivery by forceps or by version
4 Induction of labour by bag, bougie, or pack.
5 Evidence of uterine infection
6 More than six vaginal examinations
7 More than twelve rectal examinations
8 Dead or damaged fœtus

We have chosen extraperitoneal cæsarean section as the preferable mode of delivery when faced with these examples of dystocia

The cases in the present series fall into two main groups (1) those in which uterine inertia had persisted so long as to render the patient potentially or frankly infected, the cervix had not yet reached the stage of full dilatation, and the possibility of a successful vaginal delivery of a living infant had become remote, and (2) those in which cephalopelvic disproportion or malpresentation precluded the vaginal delivery of a living child, whether or no the stage of full cervical dilatation had been reached, and in which outside interference had rendered any form of transperitoneal cæsarean section dangerous

Of the 52 cases 42 (80%) were primigravidæ and 10 (20%) multiparæ Of the 10 multiparæ only 3 had living children, pregnancy having ended in stillbirth after difficult forceps delivery in 3 cases and in abortion in the remaining 4 Ages ranged from 19 to 43, average 29 8, 26 women (50%) were aged over 30

In 10 cases definite pyrexia was noted on admission to hospital. One of these women had an intra uterine

INTRA-PARTUM intra uterine infection is not so common today as it was twenty years ago Nevertheless a steady stream of patients either frankly or potentially infected as a result of either protracted labour or interference under adverse conditions still continues to flow into the obstetric beds of the specialist hospitals

Our improved methods of antenatal care and our better understanding of the mechanics of labour have undoubtedly reduced the number of such cases , but the problem of how to treat them remains as difficult as ever, and the outcome for the mother and child leaves much to be desired.

Chemotherapeutic agents and antibiotics have undoubtedly improved the immediate results so far as the mother is concerned, but they have not reduced the number of stillbirths It is far too early for us to assess how the long term results due to infection subsequent to trauma inflicted during a difficult vaginal delivery have been affected by these agents

A search, among the possible alternative methods of treatment of the difficult obstetric case of this type, for a means whereby the maternal mortality and morbidity, together with the total fœtal loss, could be reduced led one of us (F R S) in 1940 to embark on a series of extraperitoneal cæsarean sections This series has now reached a total of 52 cases and, although this is a small number (the incidence has been only 1 per 1000 deliveries), the results have been extremely encouraging

ALTERNATIVE METHODS OF TREATMENT

Sedation

Sedation is the generally accepted routine method of treating uterine inertia, and it is usually effective Nevertheless there remain cases in which no response is obtained, uterine motility is persistently sluggish, the risk of infection steadily increases, and all too often the fœtus dies before delivery by the vaginal route is possible Sedatives were given in the early stages of labour in most of the present series

Oxytocics

Œstrogens, vitamin B_1, and calcium may all improve uterine contractions, provided there is no cephalopelvic disproportion, but their action is uncertain Reid (1946) has studied the use of dilute solutions of ‘ Pituitrin ’ in an attempt to improve the strength of uterine contractions and expedite delivery In cases in which labour had lasted more than twenty hours before treatment was started only 8 6% had normal deliveries and 12 9% required a cæsarean section Reid does not mention any maternal mortality and cites only a corrected fœtal mortality of 116 5 per 1000 In a similar series (Stone 1950) 13 labours of over twenty hours' duration were treated in a like manner with 1 fœtal death and no maternal fatality There were but 2 spontaneous deliveries, 10 required operative vaginal delivery, and 1 a cæsarean section

Bradford et al (1949) concur in this and state that after thirty hours' labour there is a rapidly diminishing likelihood of spontaneous delivery, 48% requiring major operative delivery Obviously oxytocics do not yet provide a solution to our problem

Cervical Incisions

The incision of an incompletely dilated cervix, followed by forceps delivery, is a mutilating operation in which severe trauma is blindly inflicted on the woman, who runs the immediate risks of shock, hæmorrhage, and acute infection, and, all too often, becomes in later life the victim of chronic gynæcological disabilities. The injury inflicted on the cervix must also be held responsible, at least in part, for the secondary sterility so commonly found among patients thus operated on. The risks incurred by the fœtus during this operation are negligible Douglass and Graves (1948) report in [illegible] cases a maternal mortality of 1 9% and a gross fœtal loss of 24%

Craniotomy

Craniotomy will continue to be the elective method of treatment in those cases in which the fœtus has already died and can be delivered per vaginam without undue injury to the mother What of the case in which the fœtus is still alive, a vaginal delivery without some form of destructive operation is impossible, and the risks of peritonitis resulting from a transperitoneal cæsarean section are too great for it to be undertaken? Must the fœtus be sacrificed ?

There is the further problem of the case in which the child is already dead, a vaginal delivery is impracticable without unwarranted injury, and early delivery is necessary because of the mother's condition

Embryotomy does not solve these problems. Baird (1936) reported a maternal mortality of 7 2% as a sequel to these procedures

Transperitoneal Cæsarean Section

The classical operation need not be considered in these days , it already stands condemned It remains only to report the results of the transperitoneal lower uterine-segment operation Marshall (1949) reports that cases in labour for over forty eight hours without interference carry a maternal mortality of 2 49% , interference raised this figure to 4 54%, with a gross fœtal loss of 160 per 1000

Cæsarean Hysterectomy

Cæsarean hysterectomy entails much the same risks as a transperitoneal cæsarean section and, as a further disadvantage, robs the survivors of future childbearing —an important point, since most of them are primigravidæ Dieckmann (1948) reports that he performed this operation in 33 cases in which infection was suspected there were 6 cases of peritonitis, with 1 death

Extraperitoneal Cæsarean Section

A consideration of the above methods shows that none provides a satisfactory answer to our problem, and naturally one seeks a happier solution In this spirit we will analyse the possible advantages and drawbacks of extraperitoneal cæsarean section

This is a lower uterine segment operation and therefore has all the advantages attached to such a procedure. It has yet further advantages there is no intraperitoneal spill of infected liquor, and any risk of postoperative seepage through a peritoneal suture line is eliminated the likelihood of postoperative ileus is reduced , and there should be no trouble from postoperative adhesions The operation area can readily be treated with sulphonamides and antibiotics and it is easily drained

This operation is better than a difficult vaginal procedure It provides easy access to the uterus, with a clear view of the operation field permitting adequate hæmostasis and accurate coaptation of the edges of the uterine wound In discussing the merits of this operation one must not overlook the much improved fœtal salvage (see below)

Various objections have been raised to the procedure

1 The technique is difficult

THE OXYGEN PARADOX

EXPERIMENTS ON THE EFFECTS OF OXYGEN IN HUMAN ANOXIA

F LATHAM
M.D , B Sc Manc
SQUADRON LEADER, ROYAL AIR FORCE

THE giving of oxygen in anoxic states has sometimes had adverse effects, especially in the treatment of chronic cor pulmonale Also Comroe and Schmidt (1938) found that, after emergency tracheotomy for obstruction of airways, symptoms appeared which seemed to be attributable to the temporary cessation of cerebral circulation following sudden reoxygenation of the arterial blood

The mechanism of these disturbances differs in certain ways from that of the true paradox phenomenon The latter name was first applied by Ruff and Strughold (1939), and before this the condition had mostly passed unrecognised Briefly, when a person is anoxic and is suddenly supplied with an abundance of oxygen, his condition may rapidly worsen, and in severe cases there may be clonic muscular spasms or unconsciousness for up to 30 seconds Quite often the condition is more transient and it may pass unnoticed unless brought to light by special tests

The incidence of this paradox reaction in aviation has been emphasised by Schwarz and Malikiosis (1939), who described the case of a pilot who, having interrupted his supply of artificial oxygen to attend to a mechanical defect at 20,000 ft , collapsed unconscious when he began to breathe oxygen again Noell and Roeder (1943) demonstrated the reaction in decompression-chamber tests with Lottig's writing test They noted in several cases a striking deterioration in muscular coordination and mental faculties on breathing oxygen again after experimental anoxia The general deterioration ensued just after the circulation time would have indicated full arterial reoxygenation, and symptoms could still be detected up to 40 seconds later Noell et al (1943) obtained an electro encephalogram in a typical case

Baxter et al (1943), studying syncopal reactions in anoxia and their relation to epilepsy, found that some persons lost consciousness 30 seconds after breathing oxygen again, but later they assumed that these persons would have collapsed in any case if the anoxia had been allowed to continue longer Stavraky (1944) attributed this collapse to the direct depressing effect of oxygen on the central nervous system and to sudden constriction of cerebral blood-vessels caused by inhalation of oxygen in acapnic states

The physiology of this crucial postanoxic recovery stage has been inadequately covered, and the transient nature of the phenomenon has only served to increase the difficulties of investigation The paradox reaction is more easily demonstrated in normal healthy people, and is of particular interest in relation to the use of oxygen by aircrew, since several cases have been described recently which resulted from resumption of the oxygen supply after sudden anoxia due to very rapid decompression to high altitudes

The symptoms seem to be entirely due to a profound disturbance in the central nervous system The ensuing cardiovascular collapse may mask many of the primary nervous symptoms, which in mild cases consist of slight tremblings, clonic muscle cramps, malformation of letters in writing tests, and deterioration of logical thinking The onset of symptoms coincides with a change in facial colour following peripheral dilatation Noell (1947) states that in severer cases, leading to convulsions and unconsciousness, the convulsion may be a manifestation of latent epilepsy and he localises the symptoms to the extrapyramidal system and the hypothalamus

Before investigating this reaction it was necessary to assess quantitatively its true relation to the return of oxygen into the circulation A modified form of writing test, which gave a continuous indication of physical and mental integrity or impairment, was applied to a group of healthy people, and the results were correlated with the cardiovascular and blood pH changes found in succeeding experiments

WRITING TEST

It was considered necessary to use a technique which would detect immediately any sudden mental or neuromuscular change, and a modified form of Lottig's writing test appeared satisfactory Sixty anoxia tests were carried out on 52 persons, mostly healthy young aircrew and members of the laboratory staff The experiment was divided into two parts The first group of 30 persons were anoxic for 4 minutes in a large decompression chamber at a simulated altitude of 20,000 ft , and the second group, consisting of 8 of the first group and 22 other persons, for 5 minutes at the same height Standard drill was adhered to for the decompression chamber runs, several minutes being allowed at altitude on pure oxygen before the anoxia test was started As soon as the subject's oxygen tube was disconnected and his oxygen supply was turned off he was instructed to

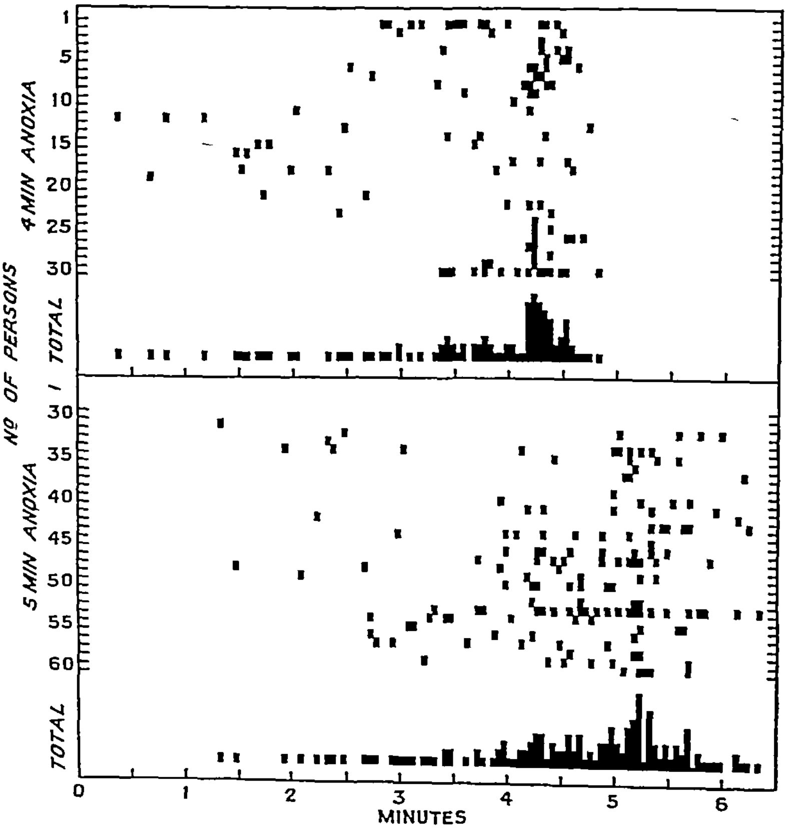

Fig 1—Errors made in 3-second periods in writing test by two groups of persons subjected to anoxia and then reoxygenated

Clostridium welchii infection, and yet was delivered of a living child

Uterine inertia was the main indication for operation in the greater part of the series, labour having been in progress for over forty eight hours in 33 cases (63%) and for over thirty six hours in 44 cases (85%) Fœtal distress was established in 34 cases (65%)

Of the fœtuses, 47 presented by the vertex and, as might be expected, there was a high incidence of occipito posterior positions The breech presented in 2 cases, the face in 1, the brow in 1, and there was 1 transverse lie Definite cephalopelvic disproportion was present in 4 cases, one of which was further complicated by prolapse of the umbilical cord

In 9 cases (17%) there had been operative interference per vaginam before section was undertaken, yet in only 1 case—that in which the face presented and attempts to correct a mentoposterior position had failed—was the cervix fully dilated

RESULTS

Maternal

There were no maternal deaths, and no patient developed peritonitis *At operation the peritoneum* had been buttonholed in 2 cases, and the bladder opened in 1 None of these cases presented undue difficulty during the puerperium

Puerperal pyrexia of notifiable degree developed in 9 patients (17%) in 6 of these it was due to an intra uterine infection, in 2 to a *Bact coli* urinary infection, and in 1 to an enteritis caused by *Salmonella aertrycke*

There was a high incidence (46%) of minor urinary infections, which, however, did not give rise to notifiable pyrexia and rapidly settled on treatment One patient developed an internal saphenous thrombophlebitis, and mild wound sepsis delayed healing of the abdominal incision in 2 cases

Fœtal

The number of children lost was 4 (7 6%) There was 1 stillbirth, the mother being an elderly primigravida whose pregnancy was complicated by essential hypertension Of the 3 neonatal deaths the first was due to atelectasis in a baby weighing 7 lb 13 oz whose mother had had pre eclampsia and accidental hæmorrhage, the second was in an infant weighing 3 lb whose mother had cholelithiasis and acute cholecystitis, and the third was in a child weighing 5 lb 8 oz who died on the seventh day from a non traumatic cerebral hæmorrhage, and whose mother had had nephrolithiasis with renal failure at the time of delivery

Well marked fœtal distress had been noted before operation in the case of the stillbirth and the death from atelectasis

Remote Sequelæ

No urinary fistulæ or any persistent disturbance of bladder function resulted from the operation Mangone (1948) made similar findings

There were no chronic wound sinuses, but 2 patients later developed incisional herniæ

Subsequent Obstetric History

Up to the time of writing, 17 patients have, between them, gone through 22 further pregnancies after the operation Of these pregnancies 16 ended in spontaneous delivery of living infants and 6 were submitted to further cæsarean section In no case was a further cæsarean section undertaken because of doubts about the security of the uterine scar, and all the scars seen at a subsequent operation were found to be sound

CONCLUSIONS

The objective of every obstetrician is to conduct the woman safely through her pregnancy and labour without damage to herself or to the baby Unfortunately, in a small proportion of cases difficulties arise that make t ideal hard to attain, and, in the past, hazardous vag deliveries have been undertaken, with disastrous re to the child and permanent injury to the mother

We consider that many of these failures can be eli nated by the use of extraperitoneal cæsarean section, a we are fortified in our belief by the results we hav obtained Similar good results have been reported b several American workers (see table)

RESULTS OF EXTRAPERITONEAL CÆSAREAN SECTION I INFECTED OR POTENTIALLY INFECTED PATIENTS

Reference	No of cases	Maternal mortality	Fœtal mortality	
			Stillbirths	Neonat deaths
Keettel and Randall (1949)	26	0	1	[illegible]
Levine and Weiner (1947)	25	1	2	0
McCall (1949)	18	0	4	1
Daichman and Pomerance (1944)	76	0	2	0
Norton (1946)	53	0	4	
Present series	52	0	1	3
Total	250	1 (*0 4%*)	14 (*5 6%*)	6 (*2 4*

McCall s 18 patients were all grossly infected We have had to reject many reported series of cases of extraperitoneal cæsarean section because the operation had been done on patients who did not fulfil Dieckmann s criteria of potential infection In yet other reports the information was too scanty for us to form a opinion

There is a definite trend nowadays towards a broadening of the range of indications for cæsarean section and this change of attitude has been justified by th results The extraperitoneal approach to the uteru permits a further justifiable extension of the indication already accepted for cæsarean section, and at the sam time leads to a reduction in the total incidence of th operation, because the surgeon may safely allow a tri of labour to proceed far longer than is the present custor

SUMMARY

The alternative methods of handling the labour o women who are potentially or actually infected ar reviewed, and the advantages and disadvantages of extr peritoneal cæsarean section are discussed The operati technique is outlined

52 mothers were operated on without fatality The was 1 stillbirth and 3 neonatal deaths

The results obtained warrant the inclusion of th operation in the armamentarium of every obstetrician.

ADDENDUM

Since writing this article we have performed the operatio on 6 further occasions, the indication in all cases w prolonged labour, with fœtal distress in 3 There was n maternal death and no case of puerperal pyrexia All th babies survived

to the back of his chair so that the observer could connect and disconnect the oxygen without the subject's knowledge The blood pressure recorder was attached to the subject's right arm, and the blood flow recorder to his left The heart-rate could be obtained from either of these recordings also At the end of each period of anoxia each subject was given 100% oxygen

Method —The blood pressure was recorded continuously by a modification of a principle first described by Doupe et al (1939) It consisted of a sphygmomanometer arm-cuff automatically blown up by an electrically operated solenoid valve actuated by signals generated from a photo electric cell placed on a finger distal to the cuff The cuff pressure followed the systolic blood pressure and in this way continuous recordings were obtained The apparatus was switched off at intervals to avoid discomfort to the subject Forearm blood flows were recorded again automatically at a rate of 6 a minute by intermittent venous occlusion plethysmography This apparatus was designed by Kerslake (1949)

Results —Blood-pressure and heart rate seemed to begin to change before symptoms referable to the central nervous system could be detected The classical blood-pressure rise of 15–20 mm Hg during anoxia was followed by a fall to normal levels in every case, beginning within 2–4 seconds after the return of oxygen This could not possibly have been a cerebral effect In three persons the blood pressure subsequently fell to subnormal levels (about 105 mm Hg) and since it was associated in these cases with a considerable rise in peripheral blood flow it was sufficient to produce faintness, dizziness, and reddening of the vision In no case did the pulse rate fall below the average resting level The greatest fall in blood pressure always established itself by the 35th second and only appeared to be significant when associated with a coincident increase in peripheral blood-flow None of the 8 persons lost consciousness The most interesting case is shown in fig 3 This subject had felt faint and confused also during a writing test Fig 4 shows the average blood pressure and peripheral blood flow in all the subjects except this one Blood flow showed no significant change during anoxia lasting 4 or 5 minutes, and a significant increase did not begin until 15 seconds after the return of oxygen, the peak appearing at the 30th second

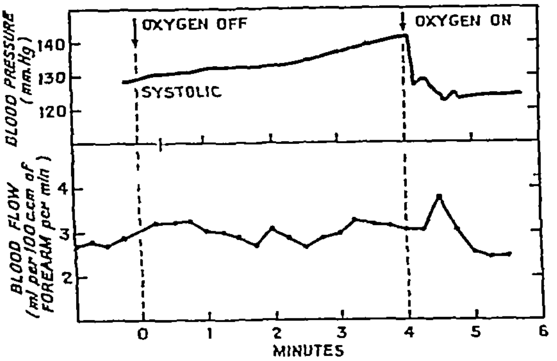

Fig 4—Average blood-pressure and peripheral blood-flow in 7 persons during recovery from 4 minutes anoxia (excluding case shown in fig 3)

BLOOD pH

It was thought that a sudden change in pH of the arterial blood brought about by sudden reoxygenation under these conditions, if coinciding with the nervous phenomena, might be the initiating factor It has also been well established that changes in the excitability of various portions of the reflex arc bear a direct relation to blood pH The magnitude of the pH change in susceptible cases was not known, so 8 persons were investigated

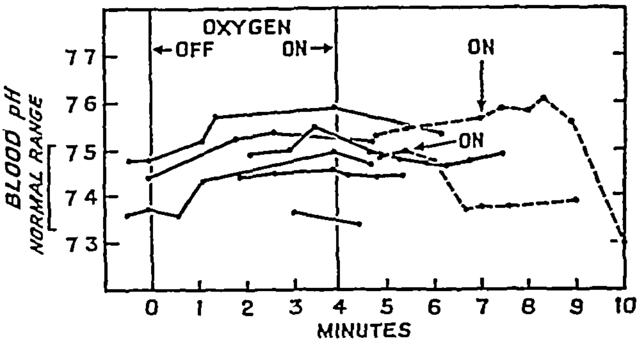

Fig 5—Changes in blood pH of 8 persons recovering from anoxia at a simulated altitude of 20,000 ft. Interrupted lines show results obtained with $5^1/_2$ and 7 minutes anoxia in 2 persons The other 6 persons underwent 4 minutes anoxia.

Method —Arterial blood samples were withdrawn anærobically at short intervals, and their pH was determined during and after anoxia at a simulated altitude of 20,000 ft The successive blood samples were immediately sealed off on removal and cooled to 0°C, and the measurements were made at 38°C within an hour of removal in a new type of miniature glass electrode cell with a capacity of 0 3 c cm The accuracy of the glass electrode was shown to be ± 0 01

Results —The outcome of the experiment suggested that the pH of the blood decreased relatively slowly after sudden reoxygenation by not more than 0 04 in the first minute of recovery (fig 5) The initial rise at the start of anoxia was not linear and seemed to follow closely the expected changes in tension of arterial carbon dioxide Of the 8 persons 2 showed premonitory signs of fainting, but their blood-pH curves did not differ from those who had no symptoms The well marked pH changes found in the person subjected to 7 minutes' anoxia (fig 5) were not shown by those subjected to 4 minutes' anoxia, and it is surprising that they were tolerated without symptoms So this person was tested again to determine the pH changes following alterations in alveolar carbon dioxide tension at ground level Fig 6 shows that, in this test, hyperventilation caused the alveolar partial pressure of carbon dioxide to decrease by at least 10 mm Hg, and the pH of the blood to increase by about 0 23, within 12 seconds The initial fall in blood pH is difficult to explain, but might have followed a short period of apnœa after the third alveolar

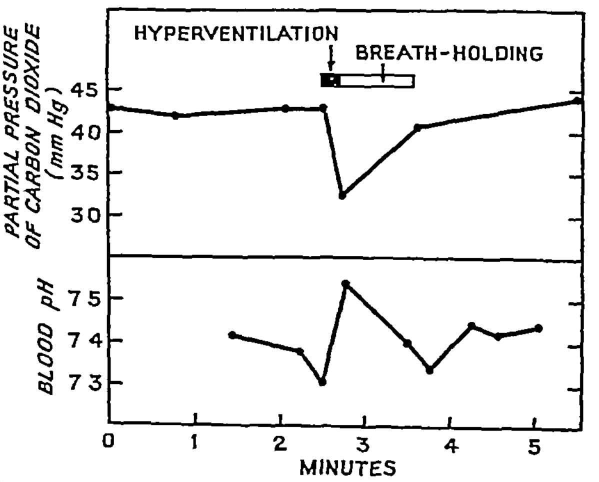

Fig 6—Changes in blood pH and carbon-dioxide tension at ground level after hyperventilation and breath-holding in the person who had undergone 7 minutes anoxia (see fig 5)

start writing Full chamber ventilation was used, and the observer maintained strict silence so that the subject's attention should not be diverted At the end of the anoxia period the subject's oxygen tube was reconnected without his knowledge At the end of the experiments the individual errors were plotted on a time scale, and the incidence of errors in each group was compared At the same time any subjective symptoms were noted by the observer, but these were not taken into account in preparing the final graph (figs 1 and 2)

Errors

This method of recording reactions did not give a complete picture of the changes taking place when the oxygen supply was resumed Subjective symptoms could not be recorded on the graph, and for this reason it is difficult to assess the number of persons showing an unmistakable paradox reaction The subjects fell broadly into four categories during the recovery stage

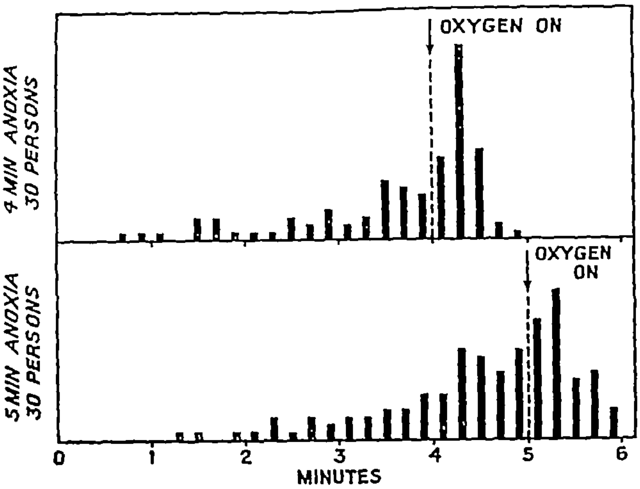

Fig 2—Errors made in 12 second periods in writing test

1 Those showing both errors and symptoms (5) See table

2 Those showing symptoms alone (3) See table

3 Those showing errors alone (5)

4 Those showing gradual recovery from anoxia without any detectable paradox reaction (39)

Categories 3 and 4 overlap and cannot be easily differentiated unless the errors show grouping during the recovery period If it is assumed that three con secutive errors after the 9th second of the recovery stage, without previous gross errors, are an adequate demonstration of the paradox reaction, at least 13 persons, including those with symptoms also, showed a paradox reaction after either 4 minutes' or 5 minutes' anoxia

If all the errors made by the 4-minute anoxia group are totalled over 3 second (fig 1) or 12 second (fig 2) periods, there seems to be a considerable increase in their incidence from the 9th to the 18th second after the oxygen was turned on This is more obvious when the graph is compared with the errors of the second group, where the anoxia was allowed to continue to the end of the 5th minute, by which time practically all of the second group were making errors The peak during their subsequent recovery stage was not so obvious, since reactors and non reactors were not adequately differentiated

To examine whether these results provide statistical proof of the paradox reaction, the sets of frequencies of errors in different time intervals may be compared as wholes The comparisons will be between the 4 minute and 5 minute anoxia groups Figs 1 and 2 show that the number of errors increased during a short interval after resumption of the oxygen supply It may be presumed that, if oxygen had not been given, the frequency of errors for the 4 minute group would have been about the same as that for the 5 minute group, since the trends for the two when both were anoxic—i e , up to 4 minutes—are very similar The mean numbers of errors for the two groups of 30 persons each from 4 minutes 9 seconds to 4 minutes 24 seconds were 1 10 for the first group and 0 47 for the second. The probability that the difference 0 63 was due to chance is shown by the *t* test to be less than 0 01 This can be accepted as good evidence that the increased number of errors following the resumption of the oxygen supply was not due to chance fluctuations.

SYMPTOMS AND ERRORS ON RESTORATION OF OXYGEN AFTER ANOXIA

Subject no	Symptoms	Time of onset after return of oxygen (sec.)	Errors
1	Faintness	30	+ -
2	Felt faint and dizzy	20	None
3	Confusion and 'alcoholic glow'	20	+
4	Faintness ' queer	20	+
5	Faintness	18	None
6	Orange visual aura	30	+ -
7	Dizziness	16	None
8	Complete confusion lasting 17 seconds	15	+

Symptoms

Of the 52 persons tested 8 had sensations varying from simple confusion to impending collapse No person became unconscious The accompanying table gives a summary of the cases

In most cases there was also a perceptible change in the handwriting after the 9th second of recovery Writing speed increased above normal and letter formation deteriorated Irregularly shaped numerals indicated tremors and loss of control of fine movements

CARDIOVASCULAR CHANGES

8 persons were subjected to anoxia at a simulated altitude of 20,000 ft , and their blood pressure and peripheral blood flow were simultaneously recorded during the progress of the anoxia and the subsequent recovery 3 of these persons repeated the experiments later, and 2 also underwent 10 minutes' anoxia at the same altitude

In each experiment the subject was seated in an arm chair, and the lead from his oxygen mask was attached

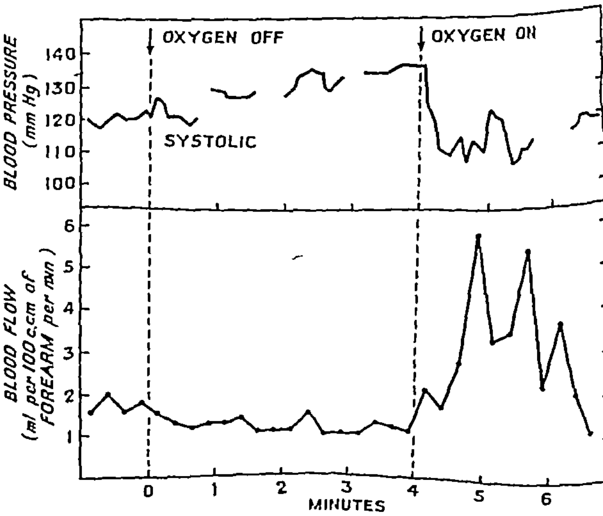

Fig 3—Cardiovascular changes during recovery from 4 minutes anoxia

9th and 12th seconds of the recovery stage from anoxia Initially it is a disturbance of the central nervous system, as manifested by an increase in writing test errors, which reaches its peak during the 12th second of recovery A slight secondary rise in the incidence of errors seems to coincide with the cardiovascular changes, which are most pronounced at about the 30th second of the recovery stage These tests have also demonstrated the onset of muscular incoördination and mental confusion developing during this period When the duration of the anoxia is increased, paradoxical symptoms in the form of faintness also increase, but the efficiency of the writing test deteriorates when the anoxia is severe

The late symptoms are those of a cardiovascular collapse associated with a fall in blood pressure and an increase in peripheral blood-flow The sequence of events is best described as follows

Systolic Blood pressure

(1) With the sudden return of oxygen there is an initial rapid fall within 2–4 seconds, which is most probably due to a rapid increase in the pulmonary vascular bed impairing cardiac filling

(2) The greatest fall in blood pressure coincided with the greatest increase in peripheral blood flow at about the 30th second

(3) Restoration to normal was usually completed within 1 minute after the return of oxygen.

Forearm Blood flow

(1) There was no significant change during the course of the 4-minute anoxia.

(2) The average curve showed a significant increase beginning 9 or 10 seconds after the return of oxygen, and this coincided with the onset of the maximum of errors

(3) Blood flow returned to previous normal levels within 60 seconds

Blood pH

Blood pH changes followed rapidly the alveolar partial pressure of carbon dioxide The average increase in pH at the end of 4 minutes anoxia amounted to 0 09 Return to normal levels was a gradual process, which in some persons took up to 4 minutes There did not seem to be any correlation between the pH changes in the arterial blood and the production of a paradoxical reaction

It is considered probable that the neurological manifestations of the paradox reaction follow a sudden impairment of cerebral circulation due to a rapid fall in systolic blood pressure when the breathing of oxygen is started again. A constitutional element is important in deciding whether the phenomenon is terminated by a cardiovascular collapse about 15 seconds after the initial onset of nervous symptoms The risk of a paradox reaction is entirely eliminated if oxygen is readministered slowly

A METHOD OF ESTIMATING THE COLLATERAL RESISTANCE DURING OBSTRUCTION OF THE MAIN ARTERY TO A LIMB

The blood flow through any limb segment depends on the local arterial pressure and the resistance offered by the peripheral vessels In normal limbs the local blood-pressure does not differ appreciably from the central pressure, but in a segment distal to an obstruction of a main artery this is not so, since the blood must traverse collateral vessels which may present a resistance comparable to that in the periphery In these circumstances the flow will be equal to the central pressure divided by the sum of the collateral and peripheral resistances Since the presence of this collateral resistance is the essential functional disability in such limbs, it is desirable to be able to estimate its magnitude In practice, as the main arterial tree becomes obstructed the peripheral resistance tends to decrease, so that measurement of the blood-flow does not allow an estimate of collateral resistance By simultaneous measurements of flow and pressures, however, such an estimate can be made

To illustrate the method a special set of circumstances was chosen where it was probable that collateral resistance was different in two limbs of one patient It has been shown that cases of osteitis deformans have a greatly increased blood-flow in the affected region (Edholm et al. 1945) and that there is an increase in the size, and possibly in the number, of arteries present (Edholm and Howarth, personal communication) A patient with osteitis deformans of the right humerus, without involvement of the left humerus or of either forearm, afforded an opportunity of studying a pair of limbs in which the arterial supply was different when the main arteries were temporarily occluded

METHOD

The method of study is shown in fig 1 A forearm and hand were enclosed in an air filled plethysmograph

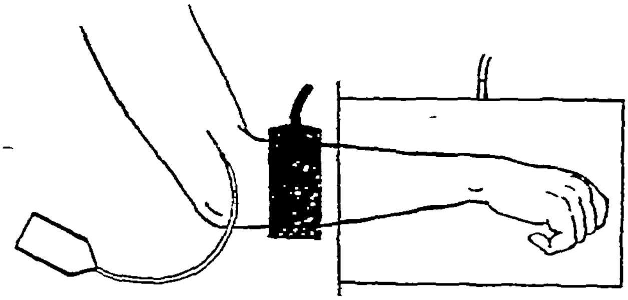

Fig 1—Plethysmograph on forearm and hand cuff on upper forearm, and needle inserted into brachial artery

A narrow cuff was placed immediately proximal to the plethysmograph just below the elbow A needle was inserted into the brachial artery at the bend of the elbow, and the pressure recorded with a condenser manometer (Hansen 1949) The brachial artery was occluded digitally about the middle of the humerus

PROCEDURE AND RESULTS

The experiment was designed to record the blood flow and blood-pressure in each arm in their normal state and sample was taken In conclusion it can be stated that the blood pH changes during the recovery stage from anoxia do not seem to bear any direct relationship to the oxygen paradox , reactors and non reactors gave similar results

DISCUSSION

The first objective change in a person suddenly reoxygenised after anoxia appears between the 9th and 12th seconds, and is predominantly a disturbance of the central nervous system, as manifested by deterioration of logical thinking, confusion, and muscular incoordination Any classical cardiovascular collapse which may develop, however, does not become established until much later, at about the 30th second of the recovery stage, and such symptoms again come under the heading of the paradox reaction, even in the absence of any preliminary detectable disturbance of the central nervous system The paradox reaction can be manifested by either or both of these distinct changes

The neurological symptoms can be explained in several ways The return of oxygen leads in every case to an immediate fall in the blood pressure, which fall impairs the cerebral circulation and consequently increases the cerebral anoxia for a while before the brain cells fully recover from their previous state The symptoms also appear at the same time that oxygenated blood first reaches the brain The possibility that a Bohr effect may lead to a temporary further increase in cerebral anoxia is not supported by the findings in the last series of experiments, which indicate that the production of a paradox reaction does not bear any relationship either to the blood-pH change due to sudden reoxygenation of the arterial blood or to the change brought about by hyperventilation during the anoxia The only other possibility is an entirely local metabolic disturbance confined to the brain cells

The rapid fall in blood pressure on reoxygenation after anoxia has been demonstrated independently on animals by many workers Grandpierre and Franck (1945) demonstrated this fall in anoxic dogs 3 or 4 seconds after the return of oxygen Similarly, von Euler and Liljestrand (1946), studying the control of the pulmonary arterial blood pressure in chloralosed cats, showed that with the return of oxygen the fall in pulmonary arterial pressure was almost immediate and was followed about 2 seconds later by a similar fall in systemic blood pressure These changes were present after extirpation of the stellate ganglion and vagotomy—i e , they were a direct effect on the lung vessels These workers also showed that, when the lung flow was doubled, there was only a 20% increase in pulmonary arterial blood pressure, demonstrating the great distensibility of the pulmonary vascular bed After reoxygenation, therefore, the high oxygen and low carbon dioxide tensions exert a local dilating effect on the pulmonary vessels This in itself would cause a sudden temporary decrease in cardiac output and fall in systemic blood pressure, and at the same time a high partial pressure of oxygen and low partial pressure of carbon dioxide in the arterial blood would cause a similar fall in blood pressure by its action on the aortic and carotid chemoreceptors This change, however, would take longer to develop and would entail peripheral blood flow changes of an equal intensity unless it was brought about by a sudden decrease in cardiac output Such a decrease in cardiac output, from a purely dynamic aspect, could only take place if there were a coincident and temporary increase in the pulmonary vascular bed and a fall in pulse rate as demonstrated It may be noted that, according to Bouckaert and Heymans (1935), carotid sinus reflexes do not affect the cerebral vasomotor tone in any active way It seems that the blood pressure changes are only significant contributory factors towards a fainting type of reaction when they are associated with a later increase in peripheral blood flow There are many factors which could give rise to the increase in blood flow observed during the recovery, and it is difficult to determine which predominates It is unfortunate that the subjects of the experiments were unable to perform the writing test simultaneously with the blood pressure and blood flow recordings during all the experiments An accurate timing of these reactions is important in referring to work carried out by Noell and Schneider (1941), who measured femoral blood flow and blood pressure in anæsthetised dogs and found a decrease in femoral blood flow with return of oxygen in anoxic animals, which was greatest after 15–20 seconds These findings are in accordance with those of Ranke (1936), Gellhorn and Steck (1938), and McMichael (1943)

The possibility of a sudden cerebral ischæmia due to local vasoconstriction appears at first sight to be sound enough Although Noell and Schneider (1941) state that cerebral blood flow only follows the systemic arterial blood pressure during anoxia, there is other evidence that high oxygen tensions in the presence of low carbon dioxide tensions cause active vasoconstriction of cerebral vessels The electro encephalograms obtained during the recovery stage from anoxia do not entirely support this theory Palme et al (1941) showed that the bioelectric changes typical of cerebral anoxia had disappeared by the end of 10 seconds after the return of oxygen If the recovery period were associated with a cerebral vasoconstriction sufficient to cause enduring cerebral anoxia, one would expect the bioelectric manifestations of anoxia to be continued long into the recovery stage, certainly over the crucial interval from the 9th to the 15th second in the paradox reaction Noell, Kornmueller, and Gremmler (1945) also found that the abnormal electro encephalographic waves typical of convulsive states only appeared after the classical picture of cerebral anoxia had disappeared

It is obvious that many factors contribute to the final outcome, and a constitutional element is important in determining whether or not the nervous manifestations of the paradoxical reaction are further complicated by circulatory collapse It seems that a person does not always produce a paradox reaction even if he has been shown to be a good reactor on a previous occasion In the light of past experience it has been found that, providing the oxygen is turned on slowly, in all cases the risk of a paradox reaction is eliminated No untoward effects in aircrew have been noted when this rule has been applied

SUMMARY AND CONCLUSIONS

60 anoxia tests were carried out on 52 people at a simulated altitude of 20,000 ft The subjects were divided into two groups, the first being anoxic for 4 minutes, and the second for 5 minutes During the performance of a modified Lottig's writing test the incidence of errors during the recovery stages was calculated and compared

Further experiments were made on 8 of these subjects to determine the precise cardiovascular changes during the recovery stage from anoxia For this purpose blood pressure, peripheral blood flow, and pulse rate were recorded with apparatus specially designed to give automatic and continuous records

A further nine experiments were made to determine the blood pH fluctuations during the course of the paradoxical reaction The measurements were made with a new micro pH cell on intermittent arterial blood samples

A paradox reaction to oxygen was demonstrated in 13 of the 52 subjects and seemed to begin between the nor Rs changed during the experiment If these assumptions are justified, the experimental points will lie on the intersections of the lines It will be seen that this requirement is approximately fulfilled

Calculation gives a value of Rc on the left some five times that on the right The difference in pressures when the cuff is inflated so as to obstruct all flow is less striking than might be expected, because the flow through the part of the arm between obstruction and cuff is greater on the diseased side Indeed Rs on the right is about a third of that on the left

The method may be applied to cases of occlusive disease of the main artery, if the artery can be entered with a needle distal to the block

SUMMARY

Blood flow and blood pressure were measured in the forearm and hand, with the main artery open and occluded, in a resting state and during reactive hyperæmia

The data allowed the calculation of the resistance of the collateral vessels with the artery occluded

An example is given of a patient with osteitis deformans of one humerus in whom collateral resistance was found to be five times greater on the normal than on the affected side

The method can be used for the study of limbs with occlusive arterial disease, provided local arterial pressure can be measured

VENEREAL DISEASES DEPARTMENT, ST MARY'S HOSPITAL, LONDON

Two years ago, McElligott et al (1948) reviewed 275 cases of early syphilis treated with penicillin and a course of neoarsphenamine and bismuth lasting from six to ten weeks The total dose of penicillin ranged from 2 4 to 4 million units in 7½–12½ days Two thirds of the male patients and half the females were treated as outpatients with penicillin in oil beeswax mixtures, the remainder being admitted to hospital and given 40,000–75,000 units of amorphous penicillin three hourly or four hourly Contrary to expectation, more failures were noted in the smaller number of patients receiving aqueous penicillin at short intervals than among those given daily injections of oil-beeswax mixtures At the time of review 54% of the total had been followed from twelve to eighteen months, 70 2% nine months or more, and 78 1% six months or more Eleven patients in this series were treated again, four of these showing recent genital lesions, and all of them positive serum reactions The possibility of reinfection rather than relapse could not be dismissed in any of the four clinical failures

To these cases we now add 286 cases treated on similar lines, and report on the follow up of the whole 561 patients and on the results of treating 183 primary and secondary cases with penicillin and bismuth alone

The comparatively high incidence of toxic effects in the previous series, and the improved quality of the available penicillins, with their very high crystalline II (G) content, encouraged us to abandon arsenicals in the treatment of early syphilis in the autumn of 1947, and up to now we have had no cause to regret our decision

Bismuth is relatively harmless and, though there is no certain evidence that a true synergism exists between it and penicillin in the treatment of early syphilis in man, the poor results of intensive and semi intensive arseno therapy without added bismuth suggest that a more slowly acting drug may be necessary to aid the immune processes in "mopping up" any straggling spirochætes We still feel that the prolongation of the total treatment time may possibly have lowered the incidence of infectious relapse, and that, in some cases, it has perhaps prevented reinfection among married couples or other regular consorts Be that as it may, the inevitable high absentee rate during the period of surveillance is probably lowered if the treatment time is not so curtailed as to bring it into contempt

Since the publication of our first paper few further attempts have been made to assess the results of combined antibiotic and metal syphilotherapy

Eames and Miller (1949) reported the results of treating 1022 Army patients with 4 000,000 units of penicillin combined with a ten week course of neoarsphenamine and bismuth Owing to demobilisation there were many defaulters from subsequent surveillance but an actuarial assessment disclosed a failure rate of 15% at eighteen months

Mann et al (1949) combined 2 400 000 units of penicillin with arsphenoxide four times weekly for five weeks and bismuth twice weekly over the same period, and of 230 patients treated 185 were followed from six to thirty months The results in 36 seronegative cases were adjudged 100% satisfactory, in 55 seropositive primaries 90% satisfactory and in 94 secondary cases 86% satisfactory

Pardo Castello and Pardo (1950) treated 47 patients with early syphilis with twenty daily injections of 500,000 units of penicillin in aqueous solution with from ten to twenty biweekly injections of subsalicylate of bismuth Of 41 patients observed from three to fifteen months 26 attained or maintained seronegativity, the remaining 15 showing no signs of relapse with a declining serological titre

O'Malley (1950) reports 365 cases of early syphilis treated with various doses of penicillin plus three or four injections of arsphenoxide and bismuth Of 86 followed for a year 4 were seroresistant and 8 showed serological relapse, 1 of which had mucocutaneous lesions in addition The failure rate was assessed at 13 95%

In both of our series we have tried to classify the known failures as relapses or reinfections after critical examination of each case In coming to a decision we have been guided by the following principles

(1) A slowly declining serological titre, even up to twelve months or longer, is no evidence of failure of treatment

(2) A continued rising serological titre after treatment is always evidence of failure, and static positive findings, in both complement fixation and precipitation tests, are most likely to be so if they persist for six months or longer

(3) A solitary genital mucocutaneous lesion on a new site with negative or declining serum reactions is probable evidence of reinfection more especially if it follows exposure with a known infectious consort A mucocutaneous relapse is almost invariably preceded by a rising titre in the serum test

in reactive hyperæmia, first with the main artery open, and secondly with the artery occluded

Identical observations were made on each arm, and the results are shown in fig 2 Resting blood flow and blood pressure were first recorded and found to be the same in both arms Blood flow and blood pressure were again recorded immediately after releasing the cuff inflated to 300 mm Hg for thirty seconds The brachial artery was then occluded, and about ten seconds later, when the blood pressure had fallen to a stable figure, the blood flow was again measured and was found to be 5 ml a minute in the normal arm and 12 ml a minute in the affected arm The blood pressure in the affected arm was higher, and greater pulsations were recorded than on the normal side After twenty seconds the forearm cuff was inflated to about 300 mm Hg This caused a rise in blood-pressure and an increase in pulsations on both sides, the rise in blood pressure being relatively greater in the normal limb During this period there was, of course, no blood-flow in the forearm and hand After thirty seconds the cuff pressure was dropped suddenly to less than 30 mm Hg, and the blood flow and blood pressure were recorded The blood flow increased, and the blood pressure decreased, on both sides The blood flow was less and the blood pressure lower in the normal limb

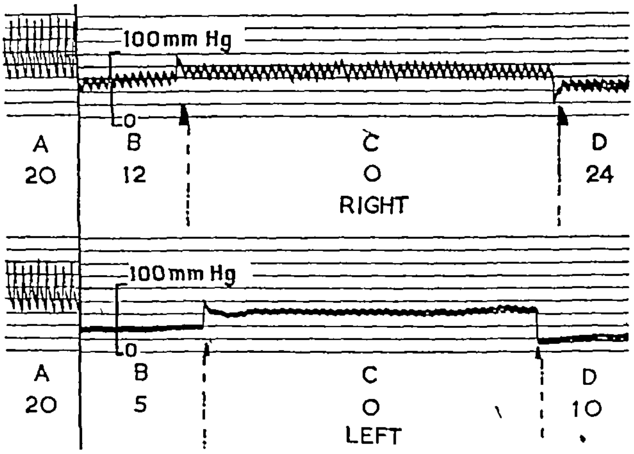

Fig 2—Upper record pressure in right brachial artery (affected limb) Lower record : pressure in left brachial artery The arteries are unobstructed during A and obstructed in the mid brachial region during B, C, and D During C the cuff was inflated to about 300 mm Hg The figures are the respective measured flows in ml per min

ANALYSIS OF RESULTS

The drop in pressure across an ideal resistance is, with appropriate units, equal to the product of the resistance and flow through it Thus, the difference between the local and central blood pressures in our experiment is equal to the value of the collateral resistance multiplied by the total blood flow in the limb distal to the obstruction We have measured the pressures, and if the flow is known the resistance can be immediately calculated In fact we have not measured the total flow through the resistance but only a part of it, since there was about 10 cm of arm between the obstruction to the brachial artery and the collecting cuff However, from the data it is still possible to calculate the resistance if certain assumptions are made The design of the experiment allows a check on the validity of these assumptions

Consider the situation when, while the artery is occluded, the cuff is inflated to a high pressure Although no blood-flow is recorded the local blood pressure is still less than the central, because some tissue above the cuff is supplied through the collaterals If the vascular resistance of these tissues is Rs, then

$$\mathrm{Rs} = \frac{\mathrm{p}}{\mathrm{P} - \mathrm{p}}\ \mathrm{Rc}$$

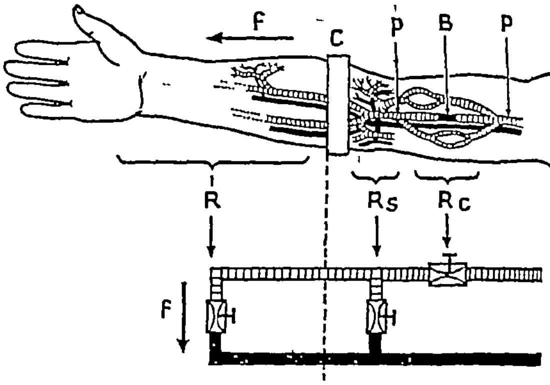

Fig 3—Diagrammatic representation of the conditions during the experiment : P, central pressure p, local pressure ; Rc, collateral resistance Rs, shunt resistance R, peripheral resistance f, measured flow B block in main artery , C, cuff

where P=the central pressure, p the local pressure under these conditions, and Rc the collateral resistance (see fig 3) If at other times a flow (f) is occurring through the part of the limb distal to the cuff, then, if Rc and Rs do not change and the local pressure is p′,

$$\mathrm{Rc}\left(\mathrm{f} + \frac{\mathrm{p}'}{\mathrm{Rs}}\right) = \mathrm{P} - \mathrm{p}'$$

Substituting for Rs as above, and solving for Rc, gives

$$\mathrm{Rc} = \frac{\mathrm{P}}{\mathrm{p}}\ \ \frac{\mathrm{p} - \mathrm{p}'}{\mathrm{f}}$$

In our experiment, besides measuring P and p, we have for each side two sets of values of p′ and f, since the flow is increased after the period of total ischæmia Hence two estimations of Rc can be made on each side In fig 4 all values for flows and pressures are plotted together with the values for either limb with the main artery unobstructed The graph may be interpreted as follows line A corresponds to the flow pressure relation in the periphery of either limb under normal conditions—i e , it represents peripheral resistance—line B represents the resistance lowered during reactive hyperæmia after thirty seconds' complete ischæmia , and lines C and D represent the pressure drop resulting in either arm by flow through the collaterals when the main artery is occluded Our assumptions are (1) that the peripheral vessels were in a similar state in both arms and reacted in the same way to thirty seconds' ischæmia , (2) that the pressure flow relationship was substantially linear over the experimental range , and (3) that neither Rc

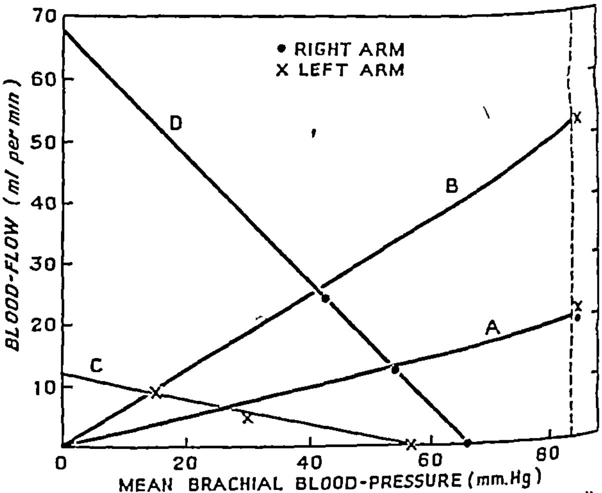

Fig 4—Pressure-flow relationship in both arms : ●, right (affected) arm ; X left (normal) arm Points on interrupted line are with artery unobstructed other points are with artery obstructed. See text.

eclamptic shortly before term, was delivered by cæsarean section of a macerated fœtus not thought to be syphilitic

Potential Failures

The 17 secondary syphilitics (14 men and 3 women) who defaulted before a decline in titre could be noted have already been mentioned and it is impossible to guess how many, if any, ultimate failures these will produce

The remaining 7 potential failures are as follows

(1) Three secondary syphilitics defaulting between four and nine months after treatment with declining serum titres

(2) One late secondary case (*T pallidum* not isolated) defaulting at eight months with a strongly positive serum titre

(3) One patient, diagnosed on clinical and historical grounds as a seropositive cervical chancre (*T pallidum* not isolated) whose serum titre had only partially declined up to the fourth month and had remained static for a further six months

(4) Two secondary syphilitics whose Wassermann reactions became negative within four months but Kahn tests were weakly positive at eighteen months Further treatment was withheld for it is our experience that such cases ultimately become completely negative

Known Failures

Two have returned nine and fifteen months after treatment with penile chancres (*T pallidum* present) but with negative serum reactions Both of these admitted re exposure from three to six weeks previously and are classed as *reinfections*

Three men whose serum tests had become negative returned nine and twelve months after treatment with dark-field positive genital lesions and positive serum reactions Although re-exposure was admitted they are classed as *relapses*

CONCLUSIONS

Patients—744 cases of early syphilis treated at St Mary's Hospital in 1946–48 are reviewed men 459 women 285, primary stage 427, secondary stage 317, dark-field positive 597, dark-field negative 147, seronegative 179, seropositive 565

Treatment—All patients had an eight-day course of penicillin, 561 receiving neoarsphenamine and bismuth in addition, and 183 added bismuth only

Toxic Effects—The only significant side-effects were those attendant on intravenous arsenotherapy

Cerebrospinal Fluid—Diagnostic lumbar punctures on 160 patients disclosed two instances of abnormality

Surveillance

229	patients were followed for	24 months or more
298	, ,	18
383		12
443	„	9
501	„	6
579		3
165		Less than 3

Results—The fact that 56 patients (7 5% of the total) defaulted while still seropositive, most of them immediately after treatment, and that only a little more than half the total have been observed for twelve months or more, deters us from attempting to calculate a percentage failure rate We are therefore content to enumerate the known failures as follows

Known reinfections	12
Known relapses	13
Weakly positive precipitation tests persisting for over nine months	3
Possible neuro-failures	2
Total	30

These figures support our opinion that eight daily injections of 500,000–600,000 units of penicillin in oil-beeswax suspension, followed by a short course of neoarsphenamine and bismuth, or of bismuth alone, is likely to be equally good treatment for early syphilis, and the fact that the early and later failure-rates do not seem to be worsening with the lapse of time is partially due to a diminishing reservoir of infectious syphilis from which reinfections could be acquired and to a steady improvement in the treponemicidal power of available penicillin preparations

Though the C S F is almost invariably normal a year or more after apparently successful treatment, 2 of 160 specimens of C S F tested showed some abnormality in seronegative patients It thus seems advisable to continue the practice of diagnostic lumbar puncture until cure is presumed

We are becoming increasingly convinced that, provided penicillin resistant strains of treponemata do not appear—and there is no evidence that they are likely to do so—the end of the arsenical era is probably at hand, and that the best treatment of syphilis in the future will be effected without the aid of these powerful albeit toxic drugs

Our thanks are due to our serologist Dr R H Gorrill and to Dr G W Csonka and the staff of the department for their help in this study

ADDENDUM

Since the submission of this article 2 further serological relapses have occurred, one twenty-four months and the other thirty-nine months after treatment The first patient a man with secondary syphilis, had received eight daily injections of 600,000 units of penicillin in oil beeswax followed by twelve of bismuth (0 2 g) at four day intervals The cerebrospinal fluid was normal at the time of relapse The second a woman with secondary syphilis, had received eight daily injections of 500 000 units of penicillin in oil beeswax followed by 4 3 g of neoarsphenamine and 3 4 g of bismuth given in twelve injections at four-day intervals Serum tests remained continually negative for thirty-four months and the C S F was normal at the time of relapse In both cases serological reversal has rapidly followed retreatment

STREPTOMYCIN IN LATENT GENITAL TUBERCULOSIS IN WOMEN

I Halbrecht
M.D Strasbourg
From the Maternity Hospital, Hadera Israel

In the past eight years the importance of genital tuberculosis in the pathogenesis of sterility in women has been firmly established[1–7] The so-called "latent" form is much the commonest, and, in contrast to the exudative form, the prognosis is almost always good On the other hand the latent form almost always gives rise to sterility which is unresponsive to treatment

The sterility in these women seems to be caused, not by the tuberculous infection of the endometrium but by partial or total occlusion of the fallopian tubes, or it may be due to the extensive changes from the early tuberculous process in the endosalpinx and the perisalpinx. Most investigators take the view that the infection is not primarily of the reproductive organs, but that these

Treatment

The total dosage of penicillin varied between 2 4 and 5 million units in eight days, the great majority receiving 500,000–600,000 units in an oil wax medium daily for eight days This was followed by an average of 4 0–4 5 g of neoarsphenamine (0 45 g every four days) and an average of about 2 0 g of bismuth (0 2 g of the oxychloride simultaneously with the arsenic)

Toxic Effects

No toxic effects of bismuth were noted, those of the penicillin were trivial, being limited to a few cases of urticaria, which were controlled with anti histamine drugs Those due to arsenic were comparatively numerous

Total	59	46

Total toxic effects 105

The incidence of jaundice in men was high and, although syringes and needles were boiled for fifteen minutes before use, this was attributed to the virus of homologous serum jaundice It is of interest, however, that 6 of these patients had previously had severe ninth day reactions

Surveillance

As was to be expected in a large metropolitan clinic with many of the patients foreigners and others casually employed, the *default rate during post treatment observation* was high, and 34 seropositive patients defaulted shortly after completion of treatment, and 5 others disappeared within six months and before becoming seronegative However, apart from these and the failures which are noted, all but 26 became seronegative within six months, and all of these achieved sero negativity within a year, 14 of them within nine months The surveillance periods were as follows

Failures

Of the 22 failures noted to date 10 have been classified as reinfections, 4 of the others relapsing with muco cutaneous lesions and the remaining 6 serologically There are also in addition 2 doubtful neuro failures Diagnostic lumbar punctures have so far been done on 146 patients, with completely normal results except in the following 2 cases

The cerebrospinal fluid (C S F) of a woman examined thirty two months after treatment showed 6 lymphocytes per c mm and a doubtful increase of globulin, all other findings including the Wassermann reaction, being negative This patient unfortunately defaulted immediately afterwards

A second woman, examined at twenty nine months, showed a paretic Lange curve, with all other findings negative In this case no treatment was given until the C S F had been twice rechecked at thirty one and forty months with similar results The patient was then treated again with 4,800,000 units of penicillin in oil beeswax in eight days, and on lumbar puncture at forty six months the C S F was normal

The significance, if any, of these two questionable recurrences of neurosyphilis is doubtful, especially in view of their negative serology, but they are both included among the failures Our known failures therefore may be classified as reinfections 10, relapses 10, and recurrences of neurosyphilis 2

Less than 1 5 g	14	18	32

Treatment

All patients received 4,800,000 units of penicillin in eight days and, except 11 cases in which two hourly injections of aqueous solutions were given, this was administered in eight daily injections of 600,000 units in an oil-wax mixture In all cases this was followed by weekly or occasionally bi weekly injections of 0 2 g of bismuth oxychloride, 151 patients being given doses of 1 5–2 5 g, and 32 less than 1 5 g Except for a few cases of urticaria, none of which, with the help of antihistaminics, was severe enough to interfere with treatment, *no adverse side effects were noted*

Up to February, 1950, 76 patients have been followed for a year or more, and over half of the total for nine months *The 55 patients* who have been followed for less than three months include 17 secondary syphilitics who defaulted before any significant decline in serum titre could be recorded, but, apart from this, all but 11 patients have become seronegative within three months and 9 of these within nine months and 2 within a year It is now our practice to postpone examination of the C S F until the second year of post treatment observation, provided that the serological response has been satisfactory, and of the specimens of *C S F so far examined* all have been found normal

Three women were given "insurance" treatment with eight daily injections of 600,000 units of procaine penicillin G because of a subsequent pregnancy The offspring of 2 of these were clinically and serologically normal at six months after birth, and the third patient, becoming pre-

BACTERIOLOGICAL CONTROL OF AUREOMYCIN THERAPY

ELIZABETH TOPLEY
M.D Lond

E J L LOWBURY
M.A, B.M Oxfd

L HURST
A I M L T

OF THE MEDICAL RESEARCH COUNCIL BURNS UNIT, BIRMINGHAM ACCIDENT HOSPITAL

IT is now recognised that 'Aureomycin' rapidly becomes inactive in nutrient media at a temperature of 37°C and at pH levels above 6 0, also that the bacteriostatic titre is considerably higher than the bactericidal titre and is markedly affected by the size of the original inoculum and the stage of growth of the culture used (Paine et al 1948) With these considerations in mind we have developed a disc assay method for detecting aureomycin in burn exudates and a ditch plate technique for testing the sensitivity of *Staphylococcus aureus*[1] to aureomycin These methods are briefly described here because they may be useful in controlling aureomycin treatment of staphylococcal and other infections Further experimental details will be reported elsewhere

DISC ASSAY METHOD FOR DETECTING AUREOMYCIN

Minimal quantities of aureomycin were detected by using Evans peptone agar at the lowest pH (5 6) and the lowest incubation temperature (25°C) which together allowed adequate growth of the indicator organism Fig 1 demonstrates the value of this low temperature and pH In laboratories without a 25°C incubator moderately satisfactory results can be obtained by using a heavy inoculum of a quickly growing indicator organism (*Bacillus cereus*),[2] incubating at 37°C, and reading the results in four hours To obtain the widest zones of inhibition, however, the lower temperature is important

With these modifications, the standard procedure of disc assay (Heatley 1949) was adopted The organism should be sensitive, as judged by the tube dilution method described below, to 0 04 µg of aureomycin per ml Many strains of *Staph aureus* and the only strain of *B cereus* that we tested are of this order of sensitivity Each organism has minor practical advantages over the other, and both are at present being used in this laboratory The stage of growth of the organism does not seem to be important, but smaller inocula have been shown to produce larger zones of inhibition around aureomycin discs A 1 in 1000 dilution of a 24 hour culture is the highest dilution that, after 24 hours' incubation on media of pH 5 6 at 25°C, gives clearly definable zones In these tests we used a phthalate acid buffer at pH 3 as solvent and diluent for aureomycin (Randall et al 1949)

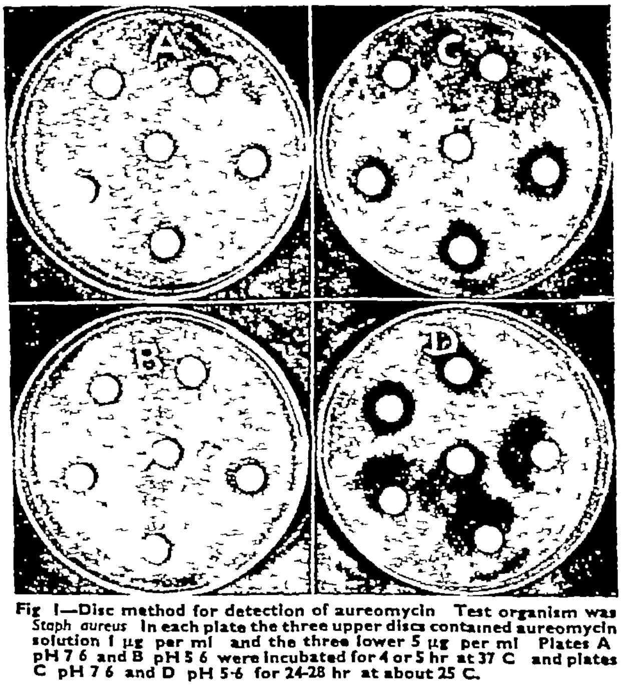

Fig 1—Disc method for detection of aureomycin Test organism was *Staph aureus* In each plate the three upper discs contained aureomycin solution 1 µg per ml and the three lower 5 µg per ml Plates A pH 7 6 and B pH 5 6 were incubated for 4 or 5 hr at 37 C and plates C pH 7 6 and D pH 5-6 for 24-28 hr at about 25 C.

Detection of Aureomycin in Burn Exudates

Discs 9 mm in diameter were cut with a cork borer from thick fluffless blotting paper dry sterilised in a hot-air oven, and stored in small petri dishes Each disc soaked up about 0 02 ml of fluid In the assay of dilutions of aureomycin this quantity was delivered from a '50 dropper' pipette immediately before assay To collect samples of exudate the discs were placed with sterile forceps on the burnt area where, within 10 seconds they soaked up exudate or blood from the raw surfaces They were also used for sampling exudate left on dressings or neighbouring skin and at necropsy for taking multiple samples from tissues and fluids —e g, bone marrow, cerebrospinal fluid, and intestinal contents

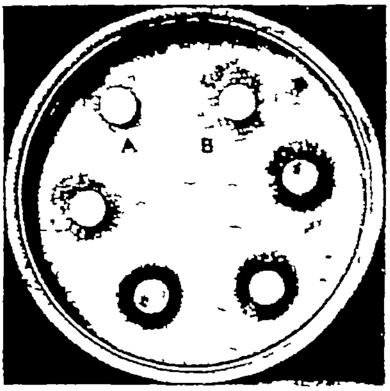

Fig 2—Detection of aureomycin in burn exudate. An undiluted 24-hr broth culture of *B cereus* was the test organism on a plate at pH 5 6 incubated for 18 hr at 25 C. Discs A and B contained 0·02 ml of aureomycin solution 1 µg and 5 µg per ml respectively the other discs had received exudate from four different burned areas on a patient treated with aureomycin 250 mg six hourly by mouth.

These discs have been assayed on plates together with discs containing known amounts of aureomycin So far, on the assumption that each disc absorbs about 0 02 ml of exudate, zones of inhibition equivalent to between 1 µg and more than 10 µg per ml have been obtained on every occasion from the 6 patients whose burn exudates were sampled while they were receiving aureomycin (at least 250 mg six hourly, see fig 2) and never from patients not receiving aureomycin

It is too early to say whether aureomycin in exudates can be assayed with any precision The experimental error of the assay method has yet to be defined, and we do not know whether the curve of zone diameter and log concentration for aureomycin in exudate is a straight line and whether it parallels that for aureomycin in phthalate buffer (Knudsen and Randall 1945)

The heat lability of aureomycin can be used to differentiate zones of inhibition produced by aureomycin from those produced by other constituents of the exudate Zones produced by aureomycin on pH 5 6 plates seeded with *Staph aureus* and incubated at 25°C become much smaller and are often eliminated if they are incubated for a further day at 37°C This reduction in size does not occur if the bactericidal agent in the exudate is, for example, a compound applied locally, such as dibromopropamidine, or the product of bacteria, such as *Pseudomonas pyocyanea*, colonising a burn For this reason it is recommended that assay plates, after incubation at are involved in a descending process from the mesenteric glands and other neighbouring organs This process attacks first the tubes and, much later, the endometrium, and it causes no symptoms Thus, when endometrial tuberculosis is discovered accidentally the anatomical changes in the tubes may be so far advanced that conception is out of the question, and in these circumstances the prospect of curing the sterility is very poor even if the tuberculous process can be arrested Nevertheless, bearing in mind the possible extension of infection to adjoining organs, one is justified in making every effort to treat the condition conservatively, however poor the prognosis for conception

---

[1] The name *Staph aureus* is used to designate any coagulase positive gram positive coccus

[2] The strain of *B cereus* (no 5) was supplied by the Lederle Laboratories Division of the American Cyanamid Company New York

MATERIAL AND METHOD

In evaluating any treatment of endometrial tuberculosis, it has to be remembered that this disease is almost always associated with endosalpingitis and/or perisalpingitis This report, however, is concerned with the treatment of endometrial tuberculosis only, and not of genital tuberculosis in general, because our methods of confirming therapeutic success or failure are limited to endometrial biopsy and to cultures from menstrual discharge

Genital tuberculosis, and particularly endometrial tuberculosis, may clear up spontaneously, so this account deals only with cases recently diagnosed and treated After treatment the result of a single endometrial biopsy is unreliable; for in serial biopsies one may be positive and the next, without further treatment, negative These negative results can only be regarded as accidental, and for this reason we have based the evaluation results not on endometrial biopsies alone but also on cultures of menstrual discharge, of which we have made as many as possible both before and after treatment

Five sterile women in whom endometrial tuberculosis was diagnosed by biopsy, and one woman whose menstrual discharge showed *Mycobacterium tuberculosis* on culture, were treated with streptomycin We made every effort to treat these cases of latent genital tuberculosis with the minimal effective doses, in order to prevent side effects Three patients received 1 g daily in two doses of 0 5 g, the other three received 1 g daily for eight days only, followed by 0 5 g daily in two doses during the rest of the course The total amount of streptomycin received by each of five out of the six cases was 40–45 g

CASE REPORTS

Case 1—Aged 20 Married 5 years, no pregnancy Bimanual examination of uterus and adnexa was negative Insufflation on Oct 7, 1947, showed the tubes to be patent Endometrial biopsy on March 27, 1948, showed normal endometrium First curettage, on June 26, revealed endometrial tuberculosis, as did a second on Oct 13 Endometrial biopsy on March 16, 1949, also gave positive proof of tuberculosis and cultures of menstrual discharges of two menses produced growth of *Myco tuberculosis*

The patient received 1 g of streptomycin daily for 75 days Endometrial biopsy on Oct 2 showed no endometrial tuberculosis, and three cultures of menstrual discharge after treatment were negative

Case 2—Aged 32 Married 10 years, sterile No history of tuberculosis Bimanual examination revealed a tumour of the left adnexa the size of an average apple Suspicion of tuberculosis was confirmed by endometrial biopsy, and two of six cultures from menstrual discharges were positive

The patient received 45 g of streptomycin spread over 45 days Thereafter endometrial biopsy showed a normal endometrium, and four cultures were negative

Case 3—Aged 30 years Married 4 years, no pregnancy At the age of 20 the patient had had pleurisy with effusion Pelvic examination showed no pathological change in uterus or adnexa Biopsy in July, 1948, showed tuberculosis of the endometrium, and of eight cultures of menstrual discharges, five showed numerous colonies of *Myco tuberculosis* The patient received altogether 45 g of streptomycin of which 8 g was given during the first 8 days and the remainder in doses of 0 5 g daily Biopsy performed after treatment was completed indicated that the endometrium was normal and five cultures were all negative

Case 4—Aged 40 years Married 10 years, no pregnancy No history of tuberculosis Genitalia normal In 1941 salpingography showed occlusion of the right tube, endometrial biopsy at this time revealed severe tuberculosis of the endometrium

This patient received 45 g of streptomycin, 20 g during the first 20 days, and the remainder in 50 days After the treatment a biopsy showed normal endometrium

Case 5—Aged 35 years Married 10 years, sterile Biopsy in 1946 showed tuberculosis of the endometrium. Pelvic examination revealed nothing abnormal except for sinistroposition of the uterus Seven cultures of the menstrual discharges between January and July, 1949, gave two positive results

This patient received 42 g of streptomycin between Sept 15 and Nov 6, 1949 Biopsy on Dec 20 revealed normal endometrium Six cultures since the end of the treatment have all been negative for tuberculosis

Case 6—Aged 39 years Married 8 years, sterile Sinistroposition of the uterus, which was otherwise normal. Three insufflations showed that the tubes were patent, and this was confirmed by salpingography Biopsy revealed normal endometrium, but three cultures of the menstrual discharges were positive for *Myco tuberculosis*

This patient received 40 g of streptomycin in 40 days and biopsy immediately after the treatment revealed endometrial tuberculosis

SUMMARY AND CONCLUSIONS

Of six confirmed cases of latent genital tuberculosis treated with streptomycin, five responded

The total dosage was 40–45 g in five cases, and 75 g in one case. The daily dosage was 1 g, but in two cases it was only 0 5 g for part of the course

These results encourage us to believe that streptomycin, even in the fairly low total dosage of 40–45 g, is effective in cases of latent genital tuberculosis The failure in one case (case 6) may have been due to insufficient dosage One advantage of this treatment is that the endometrium is preserved, and so the remote chance of subsequent pregnancy is not finally removed

The histological studies were made at the central pathological institute of the Kupath Holim, and the bacteriological studies at the central laboratories of the Kupath Holim in Tel Aviv and Haifa Special thanks are due to the directors of these institutes Dr J Casper, Dr E Bregman, and Dr L Hirsch

ADDENDUM

Since this report was completed we have successfully treated with streptomycin six further cases of latent genital tuberculosis in women, bringing the total number of cases treated to twelve

"There is, incidentally, an extraordinary disinclination to regard tuberculosis as an infectious disease, as it is, amenable to the same principles of control and prevention as other infections This attitude, despite the clear evidence of the last fifty years and the experience of other countries, is likely to prove disastrous for Scotland where tuberculosis is getting beyond control The position is far too serious to permit of tentative measures by those who have little experience of the problem"—Dr J R W HAY, medical officer of health for Kirkcaldy, in his report for 1949 consuming tube dilution technique for organisms producing zones of inhibition more than 1 mm shorter than the Oxford staphylococcus

It is not known how infection with these slightly more resistant strains (sensitive to aureomycin 0 16 μg per ml) would respond to aureomycin therapy, but the difference in their sensitivity from that of most strains may well be of no clinical significance The observation that a blood agar ditch plate technique can detect so small a difference in sensitivity indicates its presumptive value for the detection of organisms whose resistance is clinically significant The method is being used in this Unit to detect minor variations in the sensitivity of *Staph aureus* isolated from patients before, during, and after aureomycin therapy

SUMMARY

The detection of aureomycin in burn exudates by a blotting paper disc plate assay method is described The sensitivity of this test was enhanced by using agar plates at pH 5 6 and incubating the test plates at 25°C The method has the advantage of being applicable to 0 02 ml quantities of contaminated fluids

For testing the sensitivity of *Staph aureus* to aureomycin, inoculation across a blood agar plate with a ditch containing 10 μg of aureomycin per ml of agar at pH 5 6 is recommended This method detects organisms resistant to 0 04 μg of aureomycin per ml

Thanks are due to Mrs F E Brand and Mr H Lilly for technical assistance Aureomycin hydrochloride capsules (Lederle) were kindly provided by the Antibiotics Clinical Trials Committee of the Medical Research Council

TEMPORAL ARTERITIS

TWO CASES TREATED WITH AUREOMYCIN

J M RICE OXLEY
D M Oxfd, M R C P
SENIOR MEDICAL REGISTRAR

A M COOKE
D M Oxfd, F R C P
PHYSICIAN

RADCLIFFE INFIRMARY, OXFORD

SINCE first described by Horton, Magath, and Brown (1932), the syndrome of temporal arteritis has become a well recognised entity It occurs in elderly patients, over 55 years of age, and is characterised by an inflammatory reaction in the temporal arteries, with headache and signs of constitutional disturbance including fever, sweats, anorexia, and loss of weight The temporal arteries are thickened and tortuous, and the overlying skin is often reddened In some cases the disease spreads to the retinal vessels and causes disturbances of vision The white cell count may be normal or show a leucocytosis, and the erythrocyte sedimentation rate (E S.R) is almost constantly raised

The ætiology remains obscure, but in view of the inflammatory changes in the walls of the affected vessels, and the fever, infection seems to be the most likely cause We have so far seen no reports of the response of temporal arteritis to any of the known chemotherapeutic or antibiotic agents The two cases described here were treated with ' Aureomycin '

CASE RECORDS

Case 1 —A clergyman, aged 65, was admitted to the Radcliffe Infirmary on Aug 17, 1950 Three weeks earlier he had begun to get severe headaches affecting the whole of the right side of the head and face The pain was most severe in the right temporal and right occipital regions The right side of the head and face felt abnormally sensitive When the headaches started, he began to feel ill in himself, he went off his food and sweated at night Ten days before admission he had had some carious teeth removed from his right upper jaw, but the pain had remained

Past History —? Paratyphoid fever, 1919 Cholecystectomy, 1923 In October, 1949, he attended the outpatient department because of epigastric pain Barium meal and barium-enema examinations gave normal results, but he was found to have a large calcified cyst in the liver This finding, however, was thought to be unrelated to the pain He was discharged from outpatients in March, 1950, and had no recurrence of epigastric pain afterwards

On examination he looked ill, with a pale face and haggard expression, and complained of constant severe headache Temperature 102°F, pulse rate 90, respirations 20 per min Both temporal arteries were thickened, the right more than the left The skin was reddened over the frontal branch of the right temporal artery The arteries were not very tender No other abnormality was found

Investigations —Hæmoglobin 80% white blood-cells 10,000 per c mm , E S R 85 mm in 1 hour Blood culture sterile Blood urea 27 mg per 100 ml Plasma protein 6 3 g per 100 ml (albumin 3 1 g) Agglutination of salmonella and brucella negative Cerebrospinal fluid and urine normal On radiography of the chest no lesion was seen Biopsy of a section of the right temporal artery showed inflammation of the inner zone of the media and the intima There were several small foci of necrosis with giant cells closely applied to them, surrounding these were proliferating fibroblasts, occasional lymphocytes, and moderate numbers of eosinophils The adventitia showed proliferation of fibrous tissue, which seemed to vary in proportion to the severity of the medial changes

Progress —For the first week after admission the patient continued to have severe headaches and a temperature of 101° or 102°F every night The biopsy done on his seventh day in hospital was followed by an immediate and dramatic improvement in the pain His temperature after the biopsy also fell slightly, but he continued to feel ill and his appetite did not return On the twelfth day after admission treatment with aureomycin 0 5 g six hourly was begun He became afebrile in twenty four hours, but his temperature rose to 99 8°F the next night After this there was a steady improvement his appetite returned, he began to feel well, and after he had been on aureomycin for two weeks he was getting up and was symptom free His temporal arteries appeared normal, and he was afebrile except for an occasional rise of temperature to 99°F After the aureomycin was stopped, he remained well and was discharged home on Sept 13

Case 2 —A children s nurse, aged 66, unmarried, was admitted to an Oxford nursing home on June 13, 1950 Two weeks previously she had begun to feel unwell and was found to have a temperature of 100°F She stayed in bed, but there were no further symptoms Eight days before admission she had been admitted to Moreton in Marsh Hospital, where she had irregular fever up to 102°F There were then no abnormal physical signs except tenderness in the left lower quadrant of the abdomen She continued to have fever and was transferred to Oxford

On examination she had a pale complexion but did not look ill Temperature 100 6°F, pulse rate 84, respirations 20 per min Blood pressure 140/74 mm Hg No other abnormal physical findings

Investigations —Hb 66% white cells 8000 per c.mm E.S R 125 mm in 1 hour Chest radiography normal

Progress —Three days after admission she began to complain of " painful spots " on the forehead worse on the left than on the right Examination showed a striking enlargement of the temporal arteries with a nodular irregularity of outline and slight reddening of the skin over the vessels There was little tenderness The diameter of the vessels appeared to be about $^{1}/_{4}$ in The condition was more severe on the left side Other superficial vessels and the optic fundi appeared normal She remained febrile and looked progressively more ill

On June 27, two weeks after admission the temporal arteries were still enlarged and painful and treatment with aureomycin 0 5 g six hourly was started Within twenty-four hours her temperature fell and she looked better, but she began to complain of nausea Six days after the start of treatment with aureomycin the temporal arteries looked

25°C for 24 hours, should be incubated for a further day at 37°C If the zones of inhibition remain unaltered they are almost certainly produced, at least in part, by some agent other than aureomycin

The method can be made more specific for aureomycin by choosing an indicator organism that is resistant to the commonly used chemotherapeutic agents We therefore recommend the use of a penicillinase producing *Staph aureus* rather than the Oxford staphylococcus

The disc assay method is simple to use and has the advantage over dilution methods in being applicable to 0 02 ml quantities of contaminated fluid The method should be suitable not only for burn exudates but also for wound exudates, capillary blood, and other body-fluids The disc technique for sampling body fluids has been described by Koelzer and Giesen (1949), working on the assay of streptomycin, and the general conception of assaying exudates has been discussed by E J Pulaski (personal communication)

DITCH PLATE TEST FOR AUREOMYCIN SENSITIVITY

Various agar ditch and filter paper strip techniques for testing sensitivity to aureomycin have been tried With a given concentration of aureomycin (10 µg per ml), filter paper strips gave much more variable and smaller zones of inhibition than an agar ditch Incubation at 37°C was found to be better than at 25°C because, although the zone of inhibition was smaller, the result could be read with precision after 18 hours' incubation, a point of considerable practical importance It was unnecessary to adjust the whole plate to an acid reaction provided the aureomycin agar ditch was prepared with Evans peptone agar at pH 5 6 The ditches were therefore made in 10% horse blood Hedley Wright agar layered plates at pH 7 6 It was found convenient to test penicillin sensitivity on the same plate as that used for aureomycin sensitivity

Segments of blood agar are removed on opposite sides of the plate with a sterile scalpel then one ditch is filled with pH 5 6 Evans peptone agar containing 10 units of penicillin per ml. while the other is filled with the same agar containing 10 µg of aureomycin per ml The plate should be used on the day it is prepared, for otherwise the zones of inhibition may spread too far across the plate A loopful of a 24 hour broth culture of the *Staph aureus* to be tested is placed equidistant from the two ditches and spread first across one ditch and then across the other, one side of the loop being used for one ditch only In our present inquiry each plate received parallel inocula of 5 strains of *Staph aureus* and a control (the Oxford staphylococcus, which was sensitive to 0 02–0·04 µg of aureomycin per ml by the tube-dilution method) In reading the results the important measurement is the relative lengths of the zones produced by the Oxford staphylococcus and by the test strain As described below, organisms producing zones more than 1 mm shorter than that of the Oxford staphylococcus should be further tested by a tube dilution method

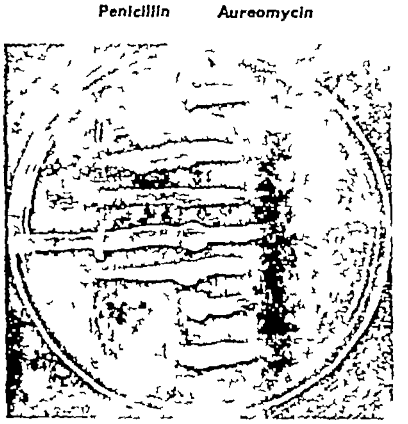

Fig 3—Double ditch-plate sensitivity test on 6 strains of Staph aureus with control above

In fig 3, from above downwards, strains 1, 6, and 7 are sensitive and 2–5 resistant to penicillin Strains 1–3 and 5–7 are sensitive to aureomycin, strain 4 gives a zone more than 1 mm shorter than the Oxford staphylococcus (strain 1,) and should be re tested by the tube dilution method

Reliability —The ditch-plate method has been used in parallel with a tube dilution method in which 0 5 ml quantities of doubling dilutions of aureomycin in pH 5 6 Evans peptone water were inoculated with 0 02 ml quantities of a 1 in 1000 dilution of the same 24 hour broth culture as was used for the plate test The tubes were incubated at 25°C for 24 hour , the end point was taken as the highest dilution with no turbidity

The accompanying table compares the results obtained with 152 strains of *Staph aureus* tested by the two methods in parallel These were the 28 available bacteriophage types[3] and 124 strains recently isolated from burns under treatment in this Unit When a strain has been tested more than once, the first result only is included Of the 152 strains tested, 140 (92%) produced zones on the ditch plate not more than 1 mm shorter than the Oxford staphylococcus and were sensitive to 0 04 µg per ml in the tube All the 28 bacteriophage types fell into this category Among the burns strains there were 7[4] which were resistant to 0 04 µg per ml in the tube, and all of them had produced zones of inhibition on the ditch plate at least 2 mm shorter than the Oxford staphylococcus, so their resistance would have been detected if this had been the only routine sensitivity test applied But there were 5 other strains of *Staph aureus* which were sensitive to 0 04 µg of aureomycin per ml but which also produced zones 2 mm shorter than the Oxford staphylococcus This discrepancy indicates the desirability of testing such strains by the tube dilution method as well as the ditch plate

COMPARISON OF BLOOD AGAR DITCH PLATE AND TUBE DILUTION METHODS FOR TESTING SENSITIVITY OF *Staph aureus* TO AUREOMYCIN

Difference in length of zones on ditch plate* (mm)	No of strains sensitive to various tube dilutions of aureomycin (µg /ml)					Total strains
	0 01	0 02	0 04	0 08	> 0 08	
+3			2			9
+2	1	3	6			10
+1	3	12	5			20
None	8	70	12			90
−1	2	11	5			18
−2	1	3		1	1	6
−3			1		2	3
−4				1	2	3
Total strains	15	99	31	2	5	152

The dotted lines divide the 12 more resistant strains from the remaining 140

* i e , length of zone of inhibition produced by test strain on blood agar ditch plate minus length of zone produced by Oxford staphylococcus

To determine the consistency of the results on individual strains all staphylococci found to be relatively resistant by the ditch plate or tube test have been retested one or more times by both techniques By the tube dilution method in every instance the strains previously sensitive to 0 04 µg per ml were again sensitive to this strength and the strains previously resistant to 0 04 µg per ml were again resistant to it, but, so far, all strains tested have been sensitive to 0 16 µg per ml By the blood agar ditch method all strains resistant to 0 04 µg per ml in the tube have, on being retested, again produced zones of clearing 2 or more mm shorter than the Oxford staphylococcus

It seems from these results that a satisfactory routine would be to test all staphylococci in the first instance by the ditch plate method, and to reserve the more time a tentative diagnosis of leptospirosis was made The patient had worked in the cellar of his house about a week before feeling ill he did not know whether the place was rat infested A course of penicillin 100 000 units three hourly was begun on Dec 27 and continued for ten days The agglutination test became positive (1/300) on Dec 29 Within twenty four hours of the first injection the patient felt very much better and his temperature became normal but jaundice and hæmaturia lasted eight days He was discharged on Jan. 12 1949, completely cured

---

[3] These were bacteriophage propagating strains kindly supplied by the Staphylococcal Reference Laboratory Colindale Their bacteriophage types were 3A, 3B 3C 6/53a, 7 29 29A, 31/44 42B/47C 42C 42D 42E 44A, 47 47A 47B 51 52 52A 31A 53 54 55 57 69 70 71 and 47D

[4] Of these 7 relatively resistant strains 4 were of bacteriophage types 47, 47/53 47/53 and 53 and 3 could not be typed with the available unconcentrated phages

Case 3 (under the care of Dr E Sanders) —A sewage worker, aged 40, reported ill on April 1 1949 That day he had a rigor followed by fever headache, and myalgia in arms and legs He came into hospital on April 7, being then very ill, with temperature 99 2°F, suffusion of eyes, asthenia jaundice, and albuminuria

The diagnosis of Weil s disease was evident and a course of intramuscular penicillin 100 000 units three hourly was started at once and continued for ten days On admission the blood urea level had been 125 mg per 100 ml but on the fifth day of treatment it fell to 44 mg per 100 ml On April 12 the serum showed agglutination of *L icterohæmorrhagiæ* in dilution up to 1/3000 with a trace at 1/10,000 The patient made rapid progress, and his temperature was normal from the second day onward Jaundice cleared after a few days and the blood urea level was normal on April 21 Liver function tests were normal on admission, but unfortunately they were not repeated during the later stages of the illness He returned home on May 3 1949

Case 4 —An electrical engineer aged 26 became suddenly ill on April 27, 1949, with severe frontal headache and generalised muscular pains About ten days before the onset he had gone swimming in the river Thames near Teddington Lock (rather flooded at the time) On April 30 (the day of admission to hospital) he vomited once and his temperature rose to 101°F When first seen he was irritable and fatigued with a dry coated tongue nausea and injected conjunctivæ and scleræ On May 2 albuminuria was found and a questionable icteric tinge of the scleræ A course of penicillin 100 000 units four hourly was given for eight days The first agglutination test was positive (1/3000) on May 4 Ten days later the titre rose to 1/10 000, with a trace of agglutination at 1/100 000 Within twelve hours of the first injection the patient became afebrile and he remained so throughout the rest of the illness Clinical improvement was most striking in this case, symptoms having disappeared within twenty four hours except for headache which persisted for several days longer, jaundice and albuminuria disappeared by the end of the penicillin course Red blood cells were seen in the urine for the last time on May 12 He was discharged from hospital on May 21, 1949

Case 5 —A man, aged 35, employed in a live sewer called in his doctor because of the sudden onset of rigor backache headache and myalgia in his arms Next day he complained of anorexia constipation and epigastric pain Albuminuria was found by the patient s doctor who sent him into hospital three days later with a provisional diagnosis of Weil s disease At examination on June 13 1949 the most noticeable features were the sallow complexion dry coated tongue, slight suffusion of eyes pyrexia and profound prostration Intramuscular penicillin was started soon after admission and continued for fifteen days (100,000 units three hourly for forty-eight hours and thereafter four hourly) On the second day of treatment jaundice and frank hæmaturia appeared, symptoms of uræmia especially lethargy became pronounced However the clinical picture soon changed for the better and on the eighth day of treatment icterus and nephritis were on the wane On July 1 the patient was normal in all respects his erythrocyte sedimentation rate (E.S.R.) was normal The agglutination test did not become positive till June 27 1949 (1/300) He was sent home on July 18

Case 6 —A plumber aged 47 employed on repairs of outside drains was admitted to hospital on Nov 11, 1949, with four days history of asthenia, pains in the legs and headache ushered in by a rigor vomiting abdominal pain, and headache Thirty six hours before admission jaundice had appeared, the urine had become a deep amber colour, and he had been pyrexial He was very ill, with temperature 97·4°F, moderate icterus and a dry tongue covered with brown fur he was perspiring freely and his liver was slightly enlarged and tender on palpation His blood pressure was 110/70 mm Hg He was drowsy and complained of fatigue aching in the legs and constipation Since no urine had been passed in the past thirty six hours, the bladder was catheterised this produced a few ounces of bile stained turbid urine in which urobilin could not be detected. Albuminuria was present

A course of penicillin was started immediately, an initial dose of 500,000 units being followed by doses of 100 000 four hourly On Nov 14 the dosage was increased to 500,000 units four hourly till Nov 29 Four hours after the first dose of penicillin the patient had a rigor with deterioration in his general condition, and his temperature rose to 100 4°F one and a half hours after the rigor began Next day no urine was passed, but the anuria was short lived and twenty four hours later urinary secretion started, on Nov 15 the output measured 110 oz The improvement in the renal condition could also be seen in the return to normal values of the blood urea which had been 220 mg per 100 ml on admission and was only 38 mg on Nov 24 Icterus however, continued to deepen until the patient s skin and mucosæ were deep golden orange It was obvious that treatment had not arrested the progress of hepatic lesions Thus, the colloidal gold reaction, negative on the day of admission, became positive (+ + + 3) on Nov 21 and the thymol turbidity test increased from 2 units (normal 0–4) to 7 units There was a febrile period (Nov 18–24) with the temperature varying from 99 6° to 101°F and signs in the chest suggesting left basal pneumonia No special treatment was given On Nov 29 penicillin was discontinued

The serological diagnosis remained uncertain until Nov 21, when the patient s serum showed agglutination of *L icterohæmorrhagiæ* in dilutions up to 1/1000 before that day the result was doubtful with agglutination in a dilution of 1/30 on Nov 16 On Dec 5 renal and liver function tests were repeated and found normal the blood urea level was 32 mg per 100 ml and a blood count was normal in all respects The patient was discharged on Dec 20

DISCUSSION

The beneficial effect of penicillin given early in Weil's disease is shown by the rapid fall of the temperature and by disappearance of such symptoms as headache, myalgia, epigastric pain and apathy, urine output, blood-urea level, white cell count, and E S R. return to normal quicker than in untreated patients No leptospira can be found in the urine twenty four hours after the first dose of penicillin

According to published reports febrile relapses do not occur in penicillin treated cases, but the febrile period in case 6 suggests that this is not always so Another interesting point in case 6 is the reaction seen a few hours after the administration of penicillin Clinically it resembled the Jarisch-Herxheimer reaction occurring in primary and secondary syphilis treated with penicillin, but no description of such reactions in Weil's disease has been published.

Though penicillin does not seem to have any effect on the course of established hepatitis, it probably protects the liver as well as the kidneys from further assaults by leptospira which might be alive and multiplying were it not for penicillin's growth inhibiting powers It has been conclusively shown, both in laboratory animals and in man, that penicillin has no inhibitory action on the formation of leptospiral antibodies in the penicillin treated infection, and thus does not interfere with the agglutination of *L icterohæmorrhagiæ* by the patient's serum

Another antibiotic effective in leptospirosis icterohæmorrhagica is 'Aureomycin,' which will probably take the place of penicillin as the drug of choice because of its efficacy when taken by mouth Heilman (1948) has reported that aureomycin is about twice as effective as penicillin in protecting hamsters from a fatal leptospiral infection

SUMMARY

An account is given of six cases of Weil's disease treated at an early stage with parenteral penicillin

normal, but nausea and sometimes vomiting became so severe that it became doubtful whether she could continue with the treatment She was therefore given 'Aludrox' 1 drachm before each dose of aureomycin This controlled the nausea but it is now known that aludrox seriously interferes with the efficacy of aureomycin treatment Four days later, after a total of ten days, the aureomycin was stopped Within forty eight hours the headache recurred, with enlargement and tenderness of the temporal arteries, and the temperature which had been about 99°F, rose to 100°F

During the next two weeks there was a gradual improvement in her condition and by July 17 the temporal arteries had once more become normal On this day the patient complained for the first time of defective vision in the right eye and was found to have a visual defect of about one third of the right half of the right visual field The left visual field was normal, and no ophthalmoscopic changes were seen For the next two weeks there was a further improvement in her general condition, and during this period since her hæmoglobin had remained at 66% and she had been unable to tolerate ferrous sulphate tablets, she was transfused with two bottles of group A blood By Aug 9 she was getting up, and expressed herself as feeling perfectly well There was no fever, little headache, and the temporal arteries were normal She was discharged on Aug 17 symptom free

DISCUSSION

There can be no doubt about the diagnosis of temporal arteritis in either of the two cases described In the first case confirmation was obtained by biopsy, and in the second case, although no biopsy was done, the clinical manifestations were conclusive In case 1 the patient improved steadily while he was on aureomycin, and the difference in his whole appearance before and after starting the drug was remarkable After two weeks he was afebrile and symptom free In case 2 the drug was badly tolerated, and its effect was less conclusive However, the fall of temperature and return to normal of the temporal arteries soon after starting treatment with aureomycin, and the relapse forty eight hours after it had to be stopped, indicated a definite influence of the drug on the disease

The disease untreated is self limited and its duration variable Horton and Magath (1937) found that in their cases the illness lasted four to six months, but Cooke et al (1946), who reviewed all the previously published reports, considered that the average duration of the disease was much longer than this The total duration of the disease in case 1 was only seven weeks, and in case 2 only eleven weeks (nine weeks from the onset of the changes in the temporal arteries) This short duration seems to be further evidence of the beneficial effect of aureomycin therapy

Although it is not claimed that the result of treatment in two cases is in any way conclusive, it is felt that the response to aureomycin was sufficiently encouraging for this remedy to be tried by other workers

SUMMARY

Two cases of temporal arteritis are described

Both patients were treated with aureomycin In one case there was a steady improvement in the patient's condition during treatment After two weeks' treatment with 0 5 g six hourly he was symptom free, and he has remained well since In the other case the aureomycin was badly tolerated and had to be withdrawn before a complete course could be given However, the patient showed considerable improvement while under treatment, and she relapsed within forty eight hours of its withdrawal

Aureomycin seems to deserve further trial in temporal arteritis

PENICILLIN IN WEIL'S DISEASE

A I Suchett Kaye
M D Paris, M R C P
SENIOR MEDICAL REGISTRAR, ST CHARLES' HOSPITAL, LONDON

Weil's disease (*Leptospirosis icterohæmorrhagica*) carries a mortality of about 20% in patients in whom liver and kidneys are seriously affected Milder cases, especially anicteric, recover spontaneously , but there is no means of foretelling early in the illness how severe the course will be Hence active treatment, with penicillin, is always indicated

Heilman and Herrell (1944) have demonstrated the curative action of penicillin in experimental leptospiral infection, and Alston and Broom (1944) its lethal effect on leptospira in vitro Chang's (1946) experimental results have, in the main, confirmed these findings and, on the basis of experiments with leptospirosis in guineapigs, he advocated for human leptospirosis a daily dosage of 250,000–300,000 units of sodium penicillin Hart (1944), Carragher (1945), Bulmer (1945), and Patterson (1947) have commented favourably on the clinical use of parenteral penicillin in Weil's disease, they have noticed rapid disappearance of leptospira from the urine and an absence of febrile relapses, but no apparent effect on the jaundice and nephritis

Experimental observation as well as clinical experience has provided ample evidence of the necessity of giving penicillin at the earliest stage of the infection The ideal would be antibiotic treatment in the preicteric phase Unfortunately the diagnosis is not then easy, especially as facilities for the rapid demonstration of leptospira are not always available The fact that the infection may occur often in people whose occupations carry no professional hazards of leptospirosis adds to the difficulties of early diagnosis Patterson (1947) wrote " The average patient [with leptospirosis icterohæmorrhagica] presents a picture of moderately severe influenza with decided conjunctival and scleral engorgement If the clinician remembers just this much he will usually make the correct diagnosis " The urine should be examined in every case of suspected Weil's disease, the finding of albuminuria strongly supports the diagnosis

The six cases of Weil's disease described here were treated with penicillin The course of penicillin was started before the seventh day of the illness—i e , before agglutination tests had become positive According to Bulmer (1945), the true value of penicillin in Weil's disease can be ascertained only by observing its effect during the preicteric phase Such observations are scanty, and the timing and results of treatment in cases 1, 2, 4, and 5 are, in this respect, of some interest.

CASE RECORDS

Case 1 —A business man, aged 27, became ill on Oct. 27, 1946, the onset being marked by rigor, generalised pains, pyrexia, and dry cough Three days later he was admitted to hospital with a temperature of 103°F He was then seriously ill , he was apathetic, with a dry coated tongue, and complained of influenza like symptoms , albuminuria was present Penicillin was given in an initial dose of 60 000 units and *continued in doses of 30,000 units three hourly* for seven days On Nov 1 jaundice appeared and blood was found in the urine These findings supported the diagnosis of Weil's disease, though the circumstances in which the infection could have occurred remained a mystery The patient s serum did not show agglutination of *L icterohæmorrhagiæ* (1/1000) till Nov 6 His temperature became normal twelve hours after starting penicillin therapy Jaundice and microscopical hæmaturia persisted for about three weeks He was discharged fit on Dec 10, 1946

Case 2 —A salesman, aged 27, fell ill on Dec 22, 1948, with fever, abdominal pain, constipation, hæmaturia, lumbago, and headache He was admitted to hospital on Dec 25 with a provisional diagnosis of acute nephritis Two days later a slight icteric tinge of scleræ was observed and soreness, dysuria, or bleeding, and whether there has been venereal contact The source of the discharge must be located, the urine tested, and threadworms and piles excluded The macroscopic appearance of the discharge is often characteristic To examine the discharge microscopically a specimen should be collected from the fornices with a long handled 'Bakelite' spoon, and a wet film should be made Elaborate methods of illumination or staining are not usually essential unless venereal disease is suspected The trichomonas is almost invariably associated with a grade 3 flora, and the monilia with a grade-1 or grade-2 flora

Treatment must be appropriate to the cause that of trichomonas and monilia being sometimes tedious Life is too short to carry out repeated vaginal paintings, and the more that treatment can be made self applicable the better Dr Jackson advocated ringing the changes on two or more methods of treatment in cases of trichomonas infestation—e g, 'Picragol' powder, 'S V C' tablets, or carbarsone suppositories, combined with douching with 'Milton' (as in veterinary practice) or with lactic acid, and, in cases where the mucosa is thin, œstrogens locally or orally Where the husband is also infected with trichomonas the wife is constantly subject to reinfection, but the treatment of the male is extremely difficult About 50% of a series of 468 women attending the Whitechapel clinic were found to be infested with trichomonas Of those thus infected, 130 had no evidence of gonorrhœa and 102 had In a series of infertile women attending the Exeter and District Women's Welfare Association clinic, the incidence of trichomonas was 15%, while in a birth control series at the same clinic it was only 5% This lends support to the view that chemical contraceptives have a deterrent effect on trichomonas

For monilia Dr Jackson recommended alkaline douches and a gentian violet, glycerin, and borax suppository For vaginitis in the very young œstrogens by mouth or locally are undoubtedly of value Non specific cervical discharges yield dramatically to treatment with the electric cautery, together with sulpha drugs by mouth or penicillin by injection

Reviews of Books

Textbook of Physiology and Biochemistry

GEORGE H BELL, B SC, M D, F R F P S G, professor of physiology, University of St Andrews, at University College, Dundee, J NORMAN DAVIDSON, M D, D SC, F R F P S G, Gardiner professor of physiological chemistry, University of Glasgow, HAROLD SCARBOROUGH, F R C P E professor of medicine, Welsh National School of Medicine Edinburgh E & S Livingstone 1950 Pp 918 45s

NOWADAYS the major techniques in clinical research are physiological, and the medical student reading physiology should grasp certain principles as a preliminary to his clinical work He should learn the way in which physiological knowledge is collected, and have some appreciation of the difficulties of biological measurement From this he should understand the arduous labour required to build up knowledge, and the tenuous and evanescent character of many of our working hypotheses, and should learn to value the open mind Selection from the vast subject is necessary in a textbook, and the facts chosen should be strictly accurate Thus the student will realise that physiology not only serves medicine but often leads the way, and that it is one of the great scientific foundations on which practice should be built

This new textbook has been compounded by an excellent team consisting of biochemist, general physiologist, and clinician all of high academic standing Those who turn to it merely for an account of modern applied physiology may at first feel disappointed For example, the chemical data are a little too isolated from discussion of the living processes, in the section on protein needs mention might have been made of Borst's finding that tissue breakdown is greatly reduced by adequate provision of calories in fat and carbohydrate, and electrocardiography is too sketchily outlined to give a solid basis for modern practice in this subject Again, Prinzmetal's recent work suggests that the importance of circus movement in auricular fibrillation and flutter has been overstressed The section on pulmonary circulation is hardly adequate, and Starling's law of the heart is erroneously stated, in a table, to be concerned somehow with changes in heart rate The mechanism of swallowing is poorly described, little reference being made to reflexes from the palate and pharynx which can be abolished in man by local anæsthesia while the motor pathway which may be involved in many diseases affecting the medulla is not given enough emphasis Some of the illustrations—such as the clinical photographs of scurvy—are not good enough to help the inexperienced reader But it is easy to pick such faults by looking for them, and all these are minor blemishes As a whole the book is sound and well up to date It gives good references particularly to human physiology, and the sections on the circulation, vitamins, and endocrinology are all satisfying It may well become the standard physiological manual for British students But if the student is really to appreciate the live character of physiology, a brief section on the limitation of many present day methods and the necessity for statistical study would be a salutary addition

Regional Dermatologic Diagnosis

ERVIN EPSTEIN, M D, consultant in dermatology and syphilology to the Oakland Area Veterans' Hospital and Mt Zion Hospital, Oakland, California London Henry Kimpton 1950 Pp 328 42s

EACH chapter deals with skin diseases that may affect a part of the body—e g, the nose, lips, or hands—and at the end of each chapter the diseases are tabulated On the title-page Dr Epstein admits that his book is not intended for specialists, and, so far as it is possible to deal with the diagnostic problems of dermatology in this way, the idea has been well carried out The value of such a work is a little doubtful, especially now that more and more so called skin diseases are proving to be symptoms of more general disorder of bodily and mental health. The dermatologist of today must be a highly trained general physician with special knowledge in his own branch, and it would be wrong to encourage students to tackle dermatology from the regional standpoint Nevertheless the harassed practitioner may find this book useful, for not only is the text lucid but the illustrations are excellent and there is much valuable information on treatment

Surgery of the Shoulder

A F DEPALMA, M D, professor of orthopædic surgery, Jefferson Medical College, Philadelphia London: J B Lippincott 1950 Pp 438 £7

ANY book dealing with disabilities of the shoulder inevitably provokes comparison with Codman's masterpiece Though Professor DePalma's work is less strictly personal, since it includes opinions and techniques from many sources, it nevertheless emerges bravely from the comparison Beautifully produced, it has first-class diagrams and X ray reproductions

The normal pathology of senescence as it affects the shoulder has been studied in a large number of subjects, and correlated with the symptoms—or lack of them—during life Gross tears of the rotator cuff and other degenerative lesions commonly found are compatible with normal function, which raises the question whether operation is not performed too often for traumatic ruptures There is an obvious difference, as Professor DePalma notes, between the slowly developing degenerative lesion and the sudden disruption which allows no time for compensating adjustments, but, he says even fresh traumatic lesions pointing to rupture of the cuff do not demand immediate exploration Many individuals so affected regain complete usefulness of the arm if the tear is not too severe" More important than the size of any tear in determining weakness in abduction is disproportion between the power of the deltoid and of the short rotators Gross lesions of the cuff may not impair function in the aged, where the deltoid is already correspondingly weak But cuff pathology is in advance of true senescence, and even a small tear in a middle aged labourer

There is ample experimental and clinical evidence of the curative value of penicillin if administered early in the disease Our aim should be to make the diagnosis on clinical grounds and start antibiotic treatment in the preicteric phase, and to confirm the diagnosis by agglutination tests later

I wish to thank Dr Thomas Hunt for his kind interest and help in the preparation of this paper

PARATYPHOID URINARY CARRIER TREATED WITH CHLORAMPHENICOL

J M KENNEDY
M B Belf, D P H.
MEDICAL SUPERINTENDENT, LODGE MOOR HOSPITAL, SHEFFIELD, LECTURER ON INFECTIOUS DISEASES IN THE UNIVERSITY OF SHEFFIELD

E L M MILLAR
M D, M Sc Sheff, D.P H.
DEPUTY MEDICAL OFFICER OF HEALTH, SHEFFIELD

THE treatment of carriers of typhoid or of paratyphoid bacteria in the fæces with chloramphenicol has so far produced little improvement, but the result achieved in the following case of a carrier of *S paratyphi B* in the urine is encouraging

A *S paratyphi B* infection broke out in Sheffield in the autumn of 1946, and one of the patients, a boy aged 8 years, was transferred from the City General Hospital to Lodge Moor Hospital on Dec 12, 1946, convalescing from paratyphoid fever *S paratyphi B*, Vi phage type 2, which was the type responsible for the epidemic, was continuously present in his urine The following treatments had no effect

March 1947 sulphaguanidine 6 g daily for seven days (total 42 g)
April 1947 sulphadiazine 6 g daily for seven days (total 42 g)
May, 1947 sulphadimidine 6 g daily for seven days (total 42 g)
June 1947 intramuscular penicillin 20 000 units three hourly for ten days (total 1 6 mega units)
July 1947 'Mandelix' 1 drachm thrice daily for fourteen days

On Sept 15, 1947, the patient was discharged home as a persistent urinary carrier of *S paratyphi B*, and the public health department of the city was notified During the next sixteen months nine urinary specimens were examined, all gave moderate or heavy growths of *S paratyphi B* and some pus cells were also present There were no red cells or casts

In August, 1948, serum agglutination with *S paratyphi-B* antigens gave the following results Vi, 1 5 +, O, 1 100 +, H (type aggn), 1 500 +, (group aggn), 1 200 +

On Jan 13, 1949, the patient was readmitted to Lodge Moor Hospital for streptomycin therapy *S paratyphi B* was isolated from the urine and examined for sensitivity, with the following results penicillin, resistant, sulphathiazole and sulphadiazine, slight inhibition, sulphadimidine, no inhibition and streptomycin, moderate inhibition

From Jan 20 to Feb 8, 1949, intramuscular streptomycin 0 5 g was given six hourly for 21 days (42 g)

On Feb 12, 1949, *S paratyphi B* was still present in the urine

From March 3 to March 23, 1949, intramuscular streptomycin 0 5 g was given six hourly for 21 days (42 g)

On March 24, 1949, *S paratyphi B* was still present in the urine and the organism now resisted more than 50 units of streptomycin, whereas originally it was inhibited by 4 units

On April 2, 1949, the boy was discharged home again as a persistent urinary carrier After his discharge from hospital specimens of urine taken at three-week intervals persistently showed *S paratyphi B* in large numbers

On March 23, 1950, the patient was readmitted t hospital for chloramphenicol therapy From April to April 10 he was given chloramphenicol 1 g thric daily His urine, examined on April 12, 17, 21, and 2 showed neither *S paratyphi-B* nor *Bact coli*

On May 1 the boy was discharged home Since the he has been under our observation, and fæcal specimen have been examined but *S paratyphi B* has never bee found Specimens of urine were examined on May *17, 24*, and *31*, and June 15, none of these grew *S para typhi B*, but *Bact coli* was grown from the specimens May 24 and 31, and a light growth of *Strep fæcalis* wa obtained from the specimen of May 17 The boy is no permitted to attend school after an absence of almo four years

Further investigation will be required before we ca safely claim to have established the powerful disinfectan qualities of chloramphenicol in urinary infection

We are deeply indebted to Dr L G Cook, directo of pathology, City General Hospital, Sheffield, for th bacteriological examinations

DEVON AND EXETER MEDICO-CHIRURGICA SOCIETY

Vaginal Discharge

AT a meeting on Dec 21 Dr MARGARET HADLE JACKSON spoke on vaginal discharge Some degree discharge, she said, is physiological, though the charact of the normal vaginal content varies according to th age of the woman Thus, microscopically, there a recognisable an infantile, a mature, and a postmenopaus (senile) type of discharge In the mature type thr distinct grades can be distinguished by their chara teristic flora, and the grade tends to remain fair constant in any particular individual

In a case of vaginal discharge it is useful to attem to classify it as (*a*) physiological, (*b*) due to hormon imbalance, or (*c*) pathological Physiological discharg are mere exaggerations of the normal secretory desquam tive processes they occur commonly in young unmarri women and demand no treatment except reassuran and occasionally a warm water or bicarbonate douch Cases due to hormonal imbalance may present with, f example, a profuse mucoid discharge with a grade flora often associated with a follicular cyst, or, if d to ovarian deficiency, with a thin discharge, a grade flora, and many squames of the basal type In th pathological group special importance attaches the age of the patient Among the infantile, where th mucosa is thin, the commonest cause of discharge vaginitis, either traumatic from foreign bodies or mastu bation, or infective, due to the gonococcus or oth organisms In the mature, other traumatic causes hav to be borne in mind—e g, rings, menstrual tampon buried sutures in a healing perineum, and fistulæ in bladder or rectum In addition one has to consider th possibility of allergic reactions to contraceptives, infestations with trichomonas, monilia, or yeasts (th last two particularly common in pregnancy and diabetes mellitus), of venereal disease, and of cervic and uterine lesions In the postmenopausal, where th mucosa has again become thin, apart from discharg due to polyps or malignant disease, one encounte atrophic vaginitis, often characterised by a profu and offensive discharge which only very rarely contai trichomonas or monilia

In investigating a case of vaginal discharge the histor is of first importance whether there is irritatio

THE LANCET

LONDON SATURDAY, JAN 13, 1951

Early Movement, Early Rising, and Early Discharge

When a method has been practised for over fifty years, it can scarcely be considered new and revolutionary. But the number of surgeons who favoured early ambulation has until lately been small—too small. Only gradually have we returned from post-Listerian complacency to physiological sanity. Lister's followers, reared on the teaching of bacteriology and immunity, seemed to look on Nature as an amiable half-wit who must be prevented from running their operations. It took the impact of a world war on a generation not yet steeped in orthodoxy to bring back the outlook of Hunter, and indeed of Lister himself, that Nature's methods, perfected over millions of centuries, are always purposeful and nearly always right.

For the past thirty years at any rate most surgeons have believed that the less an operation is allowed to interfere with the normal tenor of a patient's life the quicker and the more complete will be his recovery. Those who pass from belief to action—and it is a big step—permit their patients after operation to assume any attitude in bed they prefer, make them breathe deeply and move their arms and legs as soon as they are conscious, encourage them to sit on the edge of the bed to urinate and on a commode to defæcate, and urge them to get out of bed when the spirit moves them, the sooner the better. But this advance in practice, like all advances not conducted on the parade ground, has been on an uneven front. Some run ahead, perhaps too far. In 1946 Leithauser, whose early experience seems to have been among colleagues somewhat behind the times, suddenly saw the light, and, like many repentant converts, rushed ahead of the preacher. Not merely did he push patients out of bed as soon as they were conscious; he pushed them out of hospital as soon as they could totter. Others still lag behind. One surprising fact emerging from the papers we published last week by Dr Goodall and by Dr Payling Wright and her colleagues, is the extent to which conservative practices still linger. Dr Goodall states that "in the great majority of wards studied, the normal practice still approximates much more closely to a traditional than to an early ambulation regime." Taking an average of 155 patients in general surgical wards, he found that only about 30% were fully ambulant in contrast to nearly 50% who might have been. Dr Wright's paper deals largely with gynæcological cases, but it is interesting to note that in 3 of the 4 gastrectomies and all the 3 hernia operations included in her series the patients were still in bed after ten days.

When should a surgical patient become ambulant—i.e., walk round the ward? Surely not as soon as he recovers from the anæsthetic. He can be hustled out of bed at this stage by the taunts, exhortations, and hot-gospelling of house-officers, sisters, and physiotherapists; but how he hates it! Natural desires are a sure guide to procedure in most things—certainly in the selection of diet and the choice between activity and rest. The chief need in the immediate postoperative period is that the process of healing in recently divided and resutured tissues shall not be prejudiced. The arrest of capillary hæmorrhage, the sealing of spaces, the knitting of gaps by fibroblasts, and the bridging of incisions by epithelial cells—all these require rest, complete and uninterrupted, to the injured part, though to that part alone. This can be attained only by rest in bed, while deep breathing and leg exercises are carried out under the supervision of the physiotherapist. After four days the wound is safe against lesser strains, and it will be protected from major ones by nociceptive reflexes that do not reach the level of conscious pain. The worst strains to which a recently repaired surgical wound can be subjected are those of coughing and the use of the bedpan. On the fourth day the sensible and cooperative patient welcomes the first steps to a chair, and Dr Wright shows that it is physiologically wise for him to do so, since he has arrived at the point where further recumbency would lead to venous stasis. The main danger of the postoperative period is venous thrombosis, of which venous stasis is undoubtedly a major cause, and the infarction and embolism that may follow. Of interest in this connection is Dr Wright's observation that whereas the average rate of flow in the veins of arms and legs, as measured by the transit of radioactive saline solution, was accelerated in both her groups during the first four days, it was considerably slowed after that time in the non-ambulant group and did not return to normal till after three weeks, whereas in the ambulant group it was above the preoperative rate during the whole of this period.

Dr Goodall points out that a policy of early ambulation, adopted universally, would add 10–20% to the effective capacity of a hospital and would reduce greatly the call on nurses' time; though it would also necessitate an increase in basins, water-closets, and day space. But he does not suggest, as does Leithauser who records an average stay of 1.9 days in hospital following interval appendicectomy, that patients, having been got up, should be got out. It is essential to good surgery that a patient should remain under constant skilled supervision until the chance of any systemic or local complication is well past—i.e., for a minimum period of ten days in almost any surgical condition serious enough to demand hospital treatment. A visit to a clinic where early discharge is the rule quickly reveals that it leads to greater waste of beds, for the second and subsequent admissions take more bed-days and involve more paper work than retention till the patient is well. Hasty discharge also leads to increased morbidity, and often to a lamentable end-result.

Laboratory Study of Starvation in Volunteers

In the last decade the reappearance of famine on a grand scale in many parts of the world has provided all too much material for studying the reactions of man to gradual starvation. But because famine conditions are never ideal for accurate observations, such first-hand descriptions often lack scientific precision. These considerations led Prof. Ancel Keys and his colleagues of the University of Minnesota to study semi-starvation in volunteers under laboratory with a powerful deltoid may lead to incapacity because the humeral head can no longer be steadied against the glenoid before abduction begins

The interrelated syndromes of frozen shoulder, bicipital tenosynovitis, and calcifying degeneration of the cuff are well covered, with a proper emphasis on the importance of lesions of the long biceps tendon derived from the recent work of Hitchcock and Bechtol Of recurrent dislocation, Professor DePalma says that any operation which restricts external rotation will be curative, but he reminds us that spontaneous cure with age is the rule

The chapter on fractures and fracture dislocations of the upper end of the humerus is full of common sense The patient is more important than the local lesion, perfect anatomical reduction is not essential to rapid functional recovery, and the attempt to achieve the first may prejudice the second In much comminuted fracture dislocations the *author is prepared to excise all the head fragments and anchor* the musculotendinous cuff to the upper humeral shaft

There are sound chapters on tumours of the region, and on shoulder pain of neurogenic origin The final chapter on operative techniques is particularly helpful on arthrodesis

The book has the welcome virtue of keeping a proper balance between conservative and operative management

Asthma

CLEMENT FRANCIS, M B, surgeon and i/c of allergy clinic, Metropolitan Ear, Nose, and Throat Hospital London Heinemann Medical Books 1950 Pp 50 5*s*

THERE is a lot of interest in this miniature manual on asthma From a wide experience Dr Francis makes many wise and practical remarks about the use of drugs and anæsthetics, the indications for operation on the upper respiratory tract, and the value of skin-testing and physiotherapy He finds that the difficult cases are the aged, the aspirin-sensitive (4 6 % in 1357 cases), the inhaler addicts, and those with advanced bronchitis and emphysema To learn from the author it is not necessary to accept his conception of vasomotor instability as the main mechanism in asthma, nor does his claim for the value of nasal cauterisation rest on its alleged effect in increasing that stability An empirical treatment or one whose action is misunderstood can still be valuable The late Alexander Francis first treated asthma by cauterisation of the nasal septum in 1896 Why have not more doctors tried it? Is it prejudice or distrust of a treatment that has many of the characteristics of a ritual? Or is it that they are not convinced by the figures and the arguments? When Dr Francis claims that 76% of cases achieve complete relief or 50% improvement, the figures have a familiar ring for asthmatics Many physicians achieve results as good without the cautery, as possibly would Dr Francis if he denied this part of his treatment to a group of controls

Die Leptospirose

Eine kurze Darstellung für Ärzte, Tierärzte, und Gesundheitsbehörden W RIMPAU Munich and Berlin Urban & Schwarzenberg 1950 Pp 157 D M 10

Professor Rimpau, who was director of the State Bacteriological Research Institute at Munich until he retired in 1948, is an acknowledged authority on leptospirosis and has himself contributed much to our knowledge of the subject In this comprehensive and well-balanced review he presents detailed information on the laboratory, clinical, and epidemiological aspects of this group of diseases as they affect man

After describing the morphology of leptospires and methods of cultivation he summarises different views about the viability or otherwise of the granules seen in old cultures, which some workers believe to be a resting phase Unfortunately he does not state his own opinion Details are given of the serological techniques used in the study of leptospires in the laboratory and of the methods employed in carrying out surveys to determine the infection rate in rodent carriers Professor Rimpau assesses the value of the different tests and the significance to be attached to their results, and deals shortly with the morbid anatomy and histology of Weil's disease While rats infected with *Leptospira icterohæmorrhagiæ* remain carriers for life field mice carry *L grippotyphosa* for a few months only, and the infection rate varies greatly from year to year Evidence is accumulating that suggests the survival of the organisms in damp soil throughout the winter

In the clinical section the author differs in one important respect from most other writers The genus Leptospira contains a number of species, and it has been customary to give a distinctive name to the disease caused by each species—such as Weil's disease and canicola fever—and to group these into "severe" and "benign" forms, depending on the presence or absence of jaundice, and on the mortality-rate Professor Rimpau prefers to emphasise the essential similarities which are found in all forms of leptospirosis, pointing out that, in every case, leptospires first circulate in the blood, and then settle in the liver, kidney, and central nervous system—tissues for which they have a special affinity During the early stages there are no distinctive symptoms only thereafter do individual differences among species and strains give rise to different clinical pictures, and though some symptoms, such as jaundice or meningitis, are more commonly caused by certain species, the species of the infecting organism cannot be diagnosed on clinical evidence alone For this reason he uses the term "leptospirosis" instead of "the leptospiroses," and describes the different symptom complexes as variations on a single theme, without reference to the species involved Much can be said in favour of this viewpoint, and if, as seems possible, streptomycin or 'Aureomycin' supersedes specific antiserum as the most effective treatment, identification of the organism becomes unnecessary On the other hand, prophylaxis depends either on the use of specific vaccines, or on measures directed against the carrier hosts, and for these purposes accurate information about the species implicated is essential In stressing the unity of the symptomatology, therefore, care must be taken not to lose sight of the wide diversity of the methods of infection and hence of the means of prevention

---

An Introduction to Medical Photography (London Staples Press 1950 Pp 240 30*s*)—Miss Josephine Hunt, S R N, medical photographer at the Royal Cancer Hospital, summarises the type of work undertaken by a hospital photographic department and the equipment used Her book is not complete enough for reference purposes, but those who want to know what sort of work is involved will find it helpful The sections dealing with the responsibilities of the photographer to his patient on the one hand, and to the medical staff of the hospital on the other, are particularly to be commended

Digitalis and other Cardiotonic Drugs (2nd ed New York and London Oxford University Press 1949 Pp 245 45*s*)—Dr E R Movitt brings his review up to date with information about preparations of *Digitalis lanata*, thevetin and new as well as older preparations of *D purpurea* Squill receives a whole chapter to itself which seems hardly deserved The pharmacological action of digitalis, on which there has been important work in the past few years, is considered in detail Here as on other topics the author withholds his own opinions, though many would welcome an attempt to integrate differing views on theory and practice The style is discursive, but the bibliography is comprehensive, and the cardiologist will find good use for the book as a work of reference

Les Symptômes de la tuberculose pulmonaire et se complications (2nd ed Paris Masson 1949 Pp 983 Fr 1800)—This latest edition of Prof Edouard Rist's book o the symptoms and signs of pulmonary tuberculosis can b confidently recommended to those whose interests lie in th field It is beautifully written at a tempo one can only cal old fashioned in comparison with so many modern text whose authors apparently think it enough to convey fac without amenities of style That facts are here in abundanc can be judged from the sections on amyloidosis (25 pages on pains in the chest (23 pages), and on striæ occurring in th skin of the thorax (10 pages) The book shows evidence o wide personal experience and wide reading, and of dee thought on both It is not a students' textbook, but i contains a vast amount of information, and should tak its place on the reference shelf beside *The Pathogenesis o Tuberculosis* The footnotes are not the least of its felicities that their entry is effected by an invasive property inherent in the cells themselves, and colour is lent to this hypothesis by the identification of hyaluronidase in some mammalian tumours and one fowl tumour,[8] and of collagenase in many [9] It remains to be seen, however whether one or both of these enzymes are always produced by invasive growths, and whether they are always absent from benign growths Secretion of enzymes of the mucinase class might account for extravascular infiltration of collagen and other connective tissues, as well as for breaches in vessel walls, and the possibility that these enzymes are present in actively invasive tumours cannot be lightly dismissed

Whether enzymes destructive of connective tissue exist in tumours or not, there can be little doubt that ruptures and defects in vessel walls aid the entry of all types of embolic cell. By means of models, YOUNG and GRIFFITH [10] have studied the physical conditions that allow entry by cells lacking invasive power Their model presupposed that capillaries (represented by a thin-walled collapsible tube filled with circulating fluid) lie freely in a fluid medium (represented by a box reservoir containing the same fluid and polystyrene beads to mimic cells) Beads passed through holes into the tube only when the external pressure exceeded the pressure within the tube In this experiment an unstable equilibrium existed for a time, during which the terminal segment of the tube oscillated, alternately closing and opening as the internal pressure fell below and rose above the external pressure In living tissues, however, interstices between fibrils of connective tissue are normally filled, not with fluid, but with a jelly-like substance which liquefies locally in inflammation and œdema, and YOUNG and GRIFFITH went on to investigate what happens when the collapsible tube is surrounded by a continuous glycerin jelly With increased pressure in the tube the alkaline fluid contained in it was forced through a preformed hole into the jelly, which eventually broke up as the pressure increased When the pressure in the tube was again reduced below that in the gel (which was impregnated with phenolphthalein) masses of broken up jelly passed into the tube The model suffered from one serious limitation, of which YOUNG and GRIFFITH are aware the tube representing a capillary vessel was not, in their own words, " braced and guyed by strands of reticulin and collagen " When extravascular pressure rises, these external attachments make all the difference to the lumen of thin-walled vessels, instead of closing, as RIBBERT supposed and the model shows, the walls of the vessels are pulled apart by the fibrils This opening mechanism was first suggested by GASKELL,[11] and its existence has been confirmed by PULLINGER and FLOREY [12] Thus the conditions that co exist in life—rise of extravascular pressure with patent blood and lymph capillaries—are those shown by YOUNG and GRIFFITH to favour cell embolism

By measuring the pressure inside intratesticular grafts of Brown Pearce carcinomata and comparing it with the pressure in normal ungrafted testes of the same rabbits, YOUNG and his colleagues [13] have established that the pressure in the tumour, measured as tissue resistance to injected saline, rises during the healthy growth of grafts, whereas in a normal testis the pressure remains remarkably constant, and this implies that pressure in the tumour rises relatively to intracapillary pressure, which is assumed to be the same in both testes Only a breach in the vessel wall is then necessary for forced entry by embolic tumour cells Holes or ruptures are obviously made by hæmorrhages and by the defects often found in sinusoidal vessels of rapidly growing tumours. YOUNG and his co workers suggest that hæmorrhages may be due to a temporary rise in intravascular pressure, which causes the endothelial walls to burst mechanically It is more likely, however, that blood leaks, or is forced, out of the growing tips of the capillaries that form continuously in response to the stimulus of the ever-growing tumour, and that tumour cells enter these same tips as well as the defectively lined sinusoids Hæmorrhages in their van are a feature of growing capillaries, and the added volume of blood increases tissue pressure and stretches open neighbouring lengths of vessel These are widened also by products of inflammation—œdema fluid and plasma, and possibly fluid exuded from vessels made hyperæmic by X irradiation YOUNG and his associates draw attention to many conditions likely to increase pressure inside tumours further growth and rise of pressure as time passes, aspiration biopsies and other factors causing hæmorrhage, local anæsthetics adding fluid under tension and palpation entailing compression from without

Though none of these mechanisms can be confidently blamed for any particular metastasis in man or in animals—so capricious are the ways of tumour cells—nevertheless their capacity for harm warns us to avoid them

Danger in the Home

ON Dec 14 the *Radio Times* published a sketch to illustrate the Postmaster General's annual injunction to " post early for Christmas " It represented a little girl in a nightdress leaning across an unguarded open fire towards a Christmas stocking hanging from the mantelpiece An innocent, sentimental drawing, yet hundreds of little girls in this country are burned every year, many of them fatally, in doing just this kind of thing A document recently issued by the Ministry of Works [14] shows that in 51 out of 306 accidents to children which were studied in detail the cause was lack of a fire guard, and in a further 14 the fire guard provided was either too wide in the mesh or so flimsy that any child could knock it over Of nearly 7000 fatal accidents in the homes of England and Wales every year, about a fifth are due to burns and scalds, and of course children are the chief victims

The report is issued for the benefit of research workers and " not for general publication ', but its findings should have headlines in every popular newspaper The sources of information cover a wide area and their volume should in itself lend weight to the results of the investigation For fatal accidents the figures supplied by the Registrar-General and the conditions General summaries of their observations, which were made in 1943–44, will be found in two papers[1] and in their recent book, *The Biology of Human Starvation*[2]

The subjects of the study were 32 conscientious objectors who lived in the laboratory for a year For a control period of 3 months the men were given a diet supplying 3492 calories daily, and on this they maintained their normal health and weight Then for 6 months the calorie value was reduced to 1570 daily, in the form of potatoes, cabbage, turnips, and cereals, with only a few grammes of animal protein per week —the kind of diet that people in northern Europe consume in famines On this they lost an average of 24% of their body weight and developed the classical signs and symptoms of famine victims By the end of 6 months, however, through a remarkable series of adjustments, most of the subjects were no longer losing weight Basal metabolism now accounted for only 962 calories a day, compared with the initial 1576 calories Two thirds of this fall was attributable to the reduced mass of their metabolising tissues and the remaining third to less intense tissue metabolism A more significant fall was in the calories used up in their daily activities—from 1567 to 451 per day No change was detected in the metabolic efficiency of carrying out such standard tasks as walking on a treadmill (after the necessary corrections for loss of weight), so this last fall must be ascribed to voluntary curtailment of physical activity The men moved slowly and cautiously, climbed stairs one at a time, and eliminated all unnecessary movements—means which closely resemble those observed by LEYTON[3] in prisoners of war At the same time there were profound personality changes All the men became apathetic, depressed, and introverted, avoiding social contacts so far as possible Most of them were more emotionally irritable than before, though their overwhelming physical lethargy usually prevented any aggressive behaviour Their aversion to intellectual effort made them seem stupid, but psychological tests revealed no impairment of memory, reasoning power, or verbal and arithmetical facility

In the last 3 months of the experiment various methods of rehabilitation were compared Recovery was slow but ultimately complete When they left the institute the volunteers were normal in most of their functions, but it was another 9 months before they regained full normality They seemed to recover best on a good mixed diet of about 3500 calories daily, with light exercise Additional calories, protein supplements, and special vitamin preparations had no apparent effect on the pace of recovery

Among the more detailed observations published separately were some important ones on the tissue fluids[4] and the circulatory system[5] Nearly all the subjects developed famine œdema During semi-starvation the absolute plasma volume increased only slightly, and the total amount of extracellular fluid (thiocyanate space) was substantially unchanged But owing to the great reduction in cellular mass there was a *relative* increase in both extracellular fluid and plasma volume Throughout the experiment there was a close correlation between the volumes, expressed in ml per kg body-weight, of plasma and of extravascular fluid The observations support the view that famine œdema is a reflection of a simple disproportion between the losses of extracellular fluid and of cell mass following a defective supply of calories In the present case œdema appeared without any reduction in plasma proteins The main cardiac finding in the experiment was well-marked atrophy of the heart muscle, radiological measurements indicating an average reduction of 17% in heart volume, a similar atrophy has been noted in necropsies of famine victims The average pulse rate became progressively slower for the first 8 weeks, when the basic rate was 35 per minute, but thereafter it remained about the same The bradycardia was not an indication of heart block Electrocardiograms showed reduced voltages of deflections but no important changes in rhythm Both systolic and diastolic blood pressures fell, and, in contrast with the pulse rate, the pressures went on falling to the end of the experiment, the maximum reductions being 30 mm Hg in systolic and slightly less in diastolic These changes were completely reversed on rehabilitation, and after 32 weeks most of the cardiovascular measurements were normal Cardiac function, on the other hand, recovered more slowly, which confirms the empirical finding that famine victims need long and careful convalescence All the volunteers became slightly anæmic, with an average fall in hæmoglobin level from 15 1 to 11 7 g per 100 ml in 24 weeks The causes of this anæmia are uncertain, but it is agreed that severe anæmia in famine victims is not simply a consequence of lack of calories or animal protein, so a search must be made for infections or other factors adversely affecting the bone marrow

The results of this experiment—skilfully conceived and faultlessly executed—will be of great practical value to administrators planning relief measures as well as to doctors working in future famines And unless means are quickly found to increase the world's food supplies and distribute them more equitably,[8] periodic famines seem to be an inescapable prospect

Cell Embolism and Metastasis

THE pathways and propulsion of cells in and out of blood and lymphatic channels remain subjects for fresh inquiry, though they are as old as cellular pathology itself It appears from the work of MILES and NIVEN[7] that the passage of polymorphonuclear leucocytes outwards through capillary walls is not due simply to their motility and to physical changes of the endothelium in inflammation for such passage to take place the intravascular pressure must probably exceed that in shock, where leucocytes are not found outside capillaries in infected foci Likewise the entry of fixed cells into blood and lymphatic capillaries requires both a breach in the vessel wall and a force that detaches the cells and drives them in The trauma of bone fractures or blast will make a breach for fat emboli, but such trauma does not account for the emulsification or entry of the fat With regard to tumour cells, there is a tacit assumption of these already had diffuse peritonitis or localised abscess The urgency of early operation is further underlined by the observation that of 480 patients with a history of less than twenty four hours 46 had peritonitis in the flank or pelvis, 25 generalised peritonitis, and 9 a localised abscess It says much for the training of our younger surgeons that of the 1074 patients in this low mortality series all but 46 were operated on by registrars and house surgeons

Operative technique in this series followed the usual practice Preference was given to incisions over the site of the disease The cæcum was inturned after removal of the appendix, and in 4 cases, where this was impossible because of thick infiltration of the cæcal wall, a drainage tube was inserted through the aperture into the cæcum In a few instances the appendix could not be removed Drainage was used very sparingly Even localised abscesses were closed, and indeed abscesses gave more trouble when drained than when they were sewn up If the abscess is opened, debris is removed, and a chemotherapeutic agent is introduced, prompt healing may fairly be expected without drainage However, Moloney and his colleagues think that drainage is indicated when surgical intervention has left raw bleeding areas (the older surgeons also took this view) or when a well localised abscess has thick walls Cultures revealed most commonly *Bacterium coli*, which was sometimes the only organism isolated *Streptococcus fæcalis* and anaerobic streptococci were the next most common organisms, *Clostridium welchii* was less often found Actinomycotic filaments were not unusual in smears These organisms have varying sensitivity to chemotherapeutic agents, and so logically both the sulphonamides and antibiotics may be used at the same time Sepsis in the wounds was less when 'Nylon' was used for sewing up than when catgut was employed, and late discharge of sutures was much more common with catgut than with nylon Lung complications were very rare Only 1 patient died of pneumonia, and this was an infant who had this disease on admission There was 1 death from pulmonary embolism, 1 other patient had hæmoptysis from this cause Femoral thrombosis occurred in only 6 cases Mechanical obstruction developed in 6 patients, of whom 3 died despite further operation In view of the extensive use nowadays of intravenous infusion therapy, it is interesting to note that only 35 of 98 cases of diffuse peritonitis were deemed to need this treatment It was found that, in the absence of paralytic ileus, patients would absorb by mouth or rectum as much liquid as they required

The majority of patients had left the hospital by the twelfth day, but of the 98 patients with diffuse peritonitis 38 were kept longer than eighteen days Clearly remarkable progress has been made in the treatment of acute appendicitis

RUBELLIN A NEW CARDIAC GLYCOSIDE

In the 175 years since Withering first exploited the beneficial action of the foxglove in congestive heart-failure, the galenical preparation of digitalis, with its uncertain constitution, has successfully withstood the challenge of crystalline strophanthin and is only slowly giving ground to its more serious rival, digoxin Time will show whether rubellin, a newly isolated glycoside reported by Isaacson[1] from South Africa, should be ranked as a clinical competitor, which will bear comparison with digoxin

Rubellin has nothing to do with german measles, it is obtained from the plant *Urginea rubella*, a member of the natural order Liliaceæ The digitalis like action of this highly soluble crystalline glycoside has been demonstrated by Sapeika[2] Using ouabain as a standard, he showed that the relative potencies of the cardiac glycosides are, in descending order rubellin 121, ouabain (international anhydrous) 100, prorubellin (a sugar free glycoside obtained by acid hydrolysis of rubellin) 50 5, strophanthin 44, lanatoside C 31, digoxin 19, and digitoxin 3 6 In a concentration of 10^{-6}, rubellin had the typical digitalis effect on the isolated frog's heart, as well as on the isolated mammalian (cat and rabbit) heart and on the heart and blood pressure in the intact animal Observations in man showed that the effective dose was 0 003 mg per kg of body weight intravenously Rubellin need not be assayed biologically It was effective in patients with heart disease with either normal or abnormal rhythm, acting best in cases of auricular fibrillation and congestive failure When administered intravenously it alleviated all the urgent symptoms in 2 hours, when its full action became evident It seems to be useful in cases where, owing to vomiting or unconsciousness, it is impossible to give digitalis by mouth, and where immediate treatment of congestive cardiac failure is imperative, provided that no other digitalis drug has been given within the previous ten days, digitalis may, however, be given by mouth at the same time as intravenous rubellin

VIRUSES AND GENETICS

Variation among the viruses has attracted much attention in the past not only because of its theoretical interest but also because of its practical usefulness Thus rabies, as Gordon[1] reminds us, affords the classical example of virus modification in the laboratory put to good purpose But known types of virus variants are not always characterised by simple loss of pathogenicity on transfer from one host to another Indeed there seem to be three sorts of variants Firstly, there are those with modification of pathogenicity without alteration of antigenic characters the classical 17D strain of yellow-fever virus has for instance lost its pathogenicity in tissue culture without losing its antigenic potency, and this has made it a useful immunising agent in man Secondly, there are antigenic modifications without change in pathogenicity, as suggested by the observations of Hammon and his associates[2] on the encephalitic agent recovered from mites This, when passaged in mice, possessed the St Louis encephalitis virus antigen, yet on egg cultivation the antigen characteristic of Western equine encephalitis virus emerged Thirdly, there are alterations both of pathogenic properties and of antigenicity Such have been exemplified by variant influenza virus strains, as shown by Hirst,[3] who passaged virus direct from human material in eggs and showed the strain to be different from that derived by ferret and then mouse adaptation

The influenza viruses, as Gordon remarks, excel in their "mutability," and all the three types of variation mentioned above have been encountered in laboratory work, in addition to the O–D variation in hæmagglutinin shown by recently isolated strains of virus A The observations of Isaacs and Edney[4] on the Melbourne virus A strain make it hard to believe any longer in the "purity" of any stock virus The difficulty pointed out by Gordon in the analysis of virus genetics has lain in the past in the fact that pure clones of particles derived from a single parent particle have not been available. This difficulty was overcome by Isaacs and Edney when they passaged virus in eggs at high dilutions whereby less than half of inoculated eggs yielded virus growth At such limiting dilutions, egg fluids were either non infective, or contained virus with properties resembling the parent, or else yielded a variant strain with new records kindly provided by the coroners for North London and Liverpool have been freely used, and they tell a consistent story Of late years public attention has largely focused on road accidents, and it is harder to classify home accidents so as to make a comparison, but the following figures (for years before the derationing of petrol) are not far from the mark as representing deaths

—	On the road	In the home
1945	4005	5996
1946	4161	6287
1947	4187	6835

When the years 1943, 1944, and 1945 were studied in detail by the Domestic Accidents Panel of the Ministry of Works, it was found that just under half the deaths were due to falling, and nearly a fifth to burns and scalds In an analysis of children's deaths following accidents in the home a total of 2348 boys and 1791 girls under fifteen was recorded As might be expected, there was among boys a preponderance of "hazardous" accidents, such as falls, electric shock, and explosions, but girls showed a sad superiority in burns, especially by clothing catching fire between one and fifteen years the figures were boys 96, and girls 301 As a cause of death for children under one year, suffocation was an overwhelming cause—1026 boys and 702 girls out of totals of 1181 and 814 At other ages the noteworthy figures are the high percentage of fatal falls in women over sixty five, and of course the high rates for women between twenty and sixty five, compared with men of the same age

In the study of mainly non fatal accidents valuable information was received from a wide variety of sources, including the Birmingham Accident Hospital, the almoners of a number of London hospitals, the Edinburgh city police, and health visitors on the staffs of medical officers of health In the Birmingham Accident Hospital about 5000 domestic "accidents" patients are treated each year As the sample for examination [15] the investigator chose just under 3000 cases of accident within the home which had been treated in eight months of the year, two months being taken from each quarter It is interesting to note that falls and cuts and bumps were most frequent in the summer months, and burns and scalds in November–December The latter causes take the highest place among children under two years, but give place to other injuries when the boys begin to knock around When the proportion of accidents in a given age group was related to the proportion of the population in that age group, the following ratios were obtained

Age	0–4	5–14	15–64	65+
All accidents	2 8	1 1	0 8	1 1
Falls	2 6	0 9	0 7	1 9
Burns and scalds	4 9	1 1	0 6	0 5
Falling on fire	8 9	0 8	0 3	—
Catching clothing on fire	3 4	0 6	0 8	1 1
Pulling over hot liquids	11 3	0 2	0 1	—

One of the striking features of this analysis is the high ratio in children under four years, and it is easy to see how important and necessary it is to protect young children, especially against burns and scalds The Birmingham study also showed that in 1946 40% of the patients were children under ten years of age—double their proportion in the population—and that 4% of the people living within easy reach of the hospital received treatment for home accident. The reports from other sources—the Edinburgh Royal Infirmary, the London hospitals, and the health visitors—tell much the same tale Personal rather than structural factors are the main cause of accident, but it is clear that there are most injuries where housewives live in overcrowded and ill equipped homes they are distracted by the difficulties of keeping an eye on the children while trying to get through the day's work without confusion and disorder A long story of fighting against the heavy odds of environment often lies behind such expressions as thoughtlessness, carelessness, or negligence

The prevention of accidents in the home involves many factors, including personal instruction, propaganda, and attention to safety in construction—especially of stairs and passages, because falls are the commonest cause of injury The fact that faulty equipment is not a frequent cause of accident is no excuse for permitting dangerous things to be made and sold We know how to make gas and electric fires safe by placing guards at a proper distance from the source of heat, yet so far hardly any manufacturer has taken advantage of that knowledge We know too how the dangers of the open fire can be minimised by insisting on the legal requirements about fireguards and making sure that only approved patterns are sold Every fireplace could easily be provided with sockets to take a standard type of guard Yet we continue, year by year, to tolerate hundreds of quite unnecessary tragedies

Annotations

GENERAL PRACTICE

We cordially welcome the Central Health Services Council's appointment of a committee on general practice (see p 104) Much ground must now have been cleared by the English and Scottish councils' committees on cooperation between general practitioner and other services, and by the B M A 's general practice review committee—not to mention the reports on the subject already published We trust therefore that conclusions will be reached, and advice offered, within the period of six months that has been mentioned in the press

APPENDICITIS

The mortality of appendicitis, though it has fallen steadily since 1920, is still considerable in this country more than 1500 people died from it in 1946 A survey of 1074 cases of acute appendicitis treated at the Radcliffe Infirmary, Oxford, during the period 1925–48 goes some way towards explaining the reasons In this review Moloney and his associates [1] remark that the dangerous ages at which to suffer from appendicitis are 5–14 and after 55, and the death rate for females is 40% less than that for males One curious feature is that as the social scale is descended the number of deaths falls off Possibly some difference in the habits of the upper classes—it may be dietetic—renders them more susceptible The general mortality in the whole Oxford series was 1 4%, and, as would be expected, it was highest (6 2%) in the cases with diffuse peritonitis Of all the patients 83% were in the surgeon's hands within forty eight hours of the onset of the attack, yet 25%

THE MEDICAL CARE OF THE ELDERLY

T N RUDD
M.D Lond, M R C P
PHYSICIAN, THE BELMONT HOSPITAL, TIVERTON, DEVON

No one who reads the medical papers can fail to be impressed by the number of careful reports on conditions of the elderly, sick and healthy, in hospitals and in their own homes, throughout the country

Excellent surveys have been made by British Medical Association special committee (1947) and by Sheldon (1948) on field conditions in large centres, while the treatment and care of the chronic elderly sick in hospitals have been the subject of painstaking surveys by Thomson (1949) and many others All these authors stress, with almost monotonous regularity the rising proportion of elderly to younger members of the community to be expected as a result of increased longevity and a falling birth rate Conditions of neglect under which the aged live have been noted in this country and in the United States of America (Thewlis 1946) In support of the youngers, on whom the care of the elderly falls, Sheldon (1950) has made it clear that the wage earning community is probably bearing as heavy a burden of old age as it can tolerate

The attitude of neglect towards old age and its problems has had many causes some old people are inarticulate, and unduly passive towards their disabilities, while others are querulous and difficult, all are of diminishing significance in the community, and as such, their complaints can be more easily disregarded, furthermore, some are unpleasant in their habits While our well developed moral sense quite properly prevents us from feeling any desire to apply euthanasia to the aged sick, it is seldom strong enough to make us give human sympathy or unselfish help in their needs They are thus in some respects the counterpart of the sacred cow of the Hindus

Another cause of neglect of the old is ignorance—a failure to understand how very real their needs are A new attitude is however steadily arising, and much practical sympathy is being shown, though this is at present incoordinate Hospital inpatient and outpatient services the Red Cross, the W V S ("meals on wheels"), county council welfare organisations, and private charities are all trying to do something—in many areas with no coordinating committee

Some charities are still working on an outdated system of relief Thus some almshouse trusts give help in money, rather than in goods or service we then find old people living in almshouses in a state of neglect, and in certain areas the neglected poor may even be found inside and not outside the almshouses A capable and vigorous middle aged woman, appointed as warden, will often make a remarkable improvement in the standard of living Without having to give too much help herself she will know where to get the help needed to keep the old people well cared for

The aged poor of any neighbourhood derive help from many organisations Medical care comes from the State doctor and the district nurse, upkeep from the State (old age pensions) and from private charity (almshouses and trusts), as well as from local government sources (county council hostels and "outdoor relief'), at Christmas, gifts from private charities are added Day to day help is given by 'meals on wheels," provided either by the W V S or the local authority, and by the local authority "home helps" scheme, but in some areas these two services are given only to those who are medically certified as being "sick" Old age pensioners associations help to supervise the needs of the old, to represent their interests, and provide them with social and club facilities When an old person becomes seriously ill, he is—or should be—moved to hospital, but the hospital service (which should be merely ancillary to the greater problem of care of the aged) is quite unable to cope with the calls made on it

COORDINATION OF EFFORT

A State sponsored committee should be set up in each administrative area to promote the welfare of the aged, survey the various organisations already promoting their welfare, and assess what is needed to provide a comprehensive scheme A Government body (local or central) should be approved to receive the recommendations of these committees, and to afford them help which is beyond their own power to obtain Organisations which would be represented on the committee would include

House committees of local hospitals
Red Cross and St John organisation
W V S
Old age Pensioners' Association
Charitable trusts
Clergy
Committees of old people s homes, hostels, or clubs
Geriatric social workers
District nurses
General practitioners
County council welfare department

A careful report made by such a committee, after six months' work, would awake much public interest in the area, and this might lead each community to take a pride in its record for care of the elderly, as it does in the achievements of its football team

CLINICAL GERIATRIC PROBLEMS

The ultimate problems for scientists are the reasons for ageing, and its prevention These may never be solved, but we can at least learn more of the variations of disease in old age Important changes of attitude are now becoming general (Rudd 1950) rehabilitation, especially, has come right to the fore, but it can only be successful if based on a sound and complete diagnosis of the case—a task for experienced geriatric clinicians These need greater opportunity for investigating disease, the support of a more comprehensive specialist service in the various departments of medicine and surgery, and more knowledge of necropsy results confirming or disproving clinical findings Conferences, too, are needed on geriatric clinical problems for those practising this branch of medicine, and postgraduate courses for general practitioners anxious to apply new knowledge Family doctors should have an increased capitation-rate for this time consuming branch of their work Those with a large list of old people are hard pressed to give weekly injections of mercurial diuretics if they have a correspondingly long list of wage earners and children The general practitioner's need for increased diagnostic facilities cannot usually be met by the general hospital outpatient department geriatric outpatient departments will be required, preferably in geriatric hospitals The detailed lay-out of such a department is beyond the scope of this paper, but the principle may be outlined

Aims maintenance of health and independence of the elderly diagnosis of disease, treatment of major and minor defects

Staffing geriatric physician, geriatric nurses, physiotherapist, occupational therapist, social workers (and possibly geriatric district nurses)

Special facilities pathological examinations (a postal service would be adequate), radiology for bone and chest conditions (cases requiring more elaborate investigations could be referred to a general hospital)

In hospitals which have no physiotherapy departments, the geriatric outpatient department should be linked up with an outside physiotherapy clinic, but preferably massage should be given by personnel on the geriatric staff whose methods are geared down to the properties which thereafter bred true This technique was later used by Burnet and Lind[5] in their work on the neurotropic W S influenza virus which produces encephalitis in mice The strain was coupled up with one of several other strains which would not give rise to encephalitis and which had antigens distinct from W S The progeny of the "marriage" induced encephalitis but exhibited the antigen of the second parent, and passage at limiting dilution provided no evidence that the phenomenon was due to simple mixture An example of such a new strain was obtained by using neurotropic W S and swine influenza virus and thereafter demonstrating a neurotropic virus possessing the swine antigen Genetic recombination has, of course, already been shown in the case of the *Bacterium coli* T bacteriophages[6 7], but the demonstration of a similar phenomenon in an animal virus is new and confirmation will be eagerly awaited It seems that mutation is not the only way in which virus variants arise, and one begins to wonder how Nature, or man himself, ever manages to keep a virus unchanged in character

BRISTOL'S PROBLEM FAMILIES

"HE just lets time roll by," used to be the burden of a comic song, and in some families its underlying principle is the accepted design for living The wonder is, perhaps, not that there are such families but that there are not more of them Luckily for the rest of us they seem to be on the wane Fifty years ago Charles Booth wrote of a submerged tenth today Dr R C Wofinden[8] thinks the fraction much smaller, "probably less even than a submerged hundredth"—which goes far to allay the fear that these highly prolific, mainly unproductive, sometimes delinquent, yet often contented people are on the increase Dr Wofinden has just completed, on behalf of the Problem Families Committee of the Eugenics Society, a pilot inquiry in Bristol, and four others are planned for Luton, Rotherham, the West Riding, and Kensington, with the object of standardising a suitable method of investigation which might prove useful later to other committees, and possibly even to an interdepartmental committee interested in this subject

Though the method chosen at Bristol proved to have drawbacks, the inquiry confirmed some known facts and brought others to light Local authority officers and many voluntary agencies collaborated, and a field worker visited the 155 families studied More than half of them were housed on corporation housing estates, and some had been, or were about to be, evicted from such estates because of failure to pay the rent This seems at first glance to justify the old cry of "once a slum dweller always a slum dweller", but Dr Wofinden is at pains to remind us that this is untrue He quotes an unpublished study of 50 rehoused families made by Dr I G Davies, who traced back the history both of the successful tenants and the failures Both groups, he found, had come from the same slum conditions, but in the failures personal characteristics outweighed the influence of improved conditions In general the standard of intelligence among them was low, and they could not plan their domestic life with any system "there was a 'hand to mouth' flavour in all their actions" He concluded that they would need training in domestic methods and regular supervision if they were to become good tenants, and Dr Wofinden thinks there is much to be said for rehousing families of this kind in a 'half way house"—a reconditioned older property—and promoting them to a corporation house only when they have learned to live in a decently hygienic fashion In Bristol there was little overcrowding, in the official sense, despite the fact that the problem families were often large the average number of children was 5 8 per family But they were sociable, and apt to crowd into one or two rooms—the more readily since there was seldom much in the way of furniture to attract them into the others The children, nearly all of them dirty, verminous, ill clad, and ill shod, were almost uniformly—and somewhat disconcertingly—happy The Curtis Committee laid much stress on the importance of family life, especially happy family life, so the problem becomes, as Dr Wofinden says, how to reclaim the family without breaking it up

Of the fathers, mainly unskilled and semi skilled workers, less than half were in steady employment, and the rest took what casual employment they could get, or did not care for any work Rather more than half were mentally subnormal, and about a quarter had a weak moral record in which such things as chronic alcoholism, imprisonment, bigamy, and incest figured. Others had psychological or physical defects More than half the mothers appeared to be in poor health, and three quarters of them were mentally subnormal No less than 101 of the 882 children of these 155 families are in mental defective institutions, approved schools, special schools, or residential children's homes, or boarded out with foster parents Thus 11 4% have become a direct charge on the State The rates of juvenile delinquency and of illegitimacy were high Other studies have revealed a high infant mortality rate in such families as these, but in Bristol the rate was not significantly higher among them than among other families in the city

Dr Wofinden suggests that the welfare services departments of the local authorities should be made responsible for problem families in their areas, and that they should work in close touch with the health department A small committee of officers might be set up, representing the health, housing, welfare, education, and children's departments, and with some coopted representatives of voluntary bodies, to confer on the needs of these families. He also considers that convalescent care should be available for ailing mothers, and that social reablement centres should be set up where mothers can be admitted for a time, with their families, and given some training in their job Home advisers, who will go into the homes and actually help with the housework while they teach, have proved their value, and should be more widely used. Where furniture is needed he thinks the local authority should be able to give or lend it He believes that these measures, with a realistic rehousing policy based on the "half way house," would go far towards reducing the submerged hundredth to a still smaller fraction

EGYPTIAN SILVER JUBILEE

THE 25th anniversary of the foundation of the Fuad I University, Cairo, was celebrated on Dec 27 in the presence of H M King Farouk Addresses of congratulation were presented by the vice chancellors of the universities of Oxford and Cambridge, the president of the Royal College of Physicians, the junior vice president of the Royal College of Surgeons, and the president of the Royal College of Obstetricians and Gynæcologists The honorary degree of doctor of medicine was conferred on Dr Russell Brain, that of master of surgery on Sir Cecil Wakeley (in absentia) and Mr Philip Mitchiner, and that of master of gynæcology on Prof Hilda Lloyd The new graduates were invested by Dr Mooro Pasha, dean of the faculty of medicine

Visit of H M Queen Mary

usually on some subject suggested by one or other of the boys; prayers follow. Letters from boys who have left the school show how often some point or other in the little homily goes home; at all events this family gathering in the evenings is remembered by many with serious affection as the centre point of life in the school.

But moral standards have to be acquired at many levels. The newcomer to the school sees no harm in pinching cigarettes or fruit; so the first simple device is to ensure that he finds it does not pay. The boy who takes twenty cigarettes is made to pay back thirty; the boy who steals fruit is compelled to pay for it at retail price, though by honest trading he could have it at the wholesale rate. But while he is learning, at this level, that by cheating he only robs himself, he is also beginning to find how pleasant it is to be trusted and praised; and self-interest as an incentive is gradually displaced by self-respect. Senior boys can become prefects (though without powers to inflict punishment accorded to prefects in public schools); and those who are due for discharge in a few months time graduate into the "discharge house," where they have their own dormitory and sitting-room, wear long grey flannels and marvellous "discharge" ties, and need no resident master to supervise them.

PENALTIES

Human nature is not amenable to pure reason. Before any of us gives up the egoism with which he was born, and consents to live socially, he must concede that there is "no future" (as the Cotswold schoolboys say) in crime, or even in antisocial behaviour. Mr Joyce has found that, with some boys, penalties can be used constructively to teach this elementary fact. Feeding penalties are now forbidden (as indeed they should be for growing children) but he does make use of detention for the determined rebels. The boy who defiantly refuses to do his work goes into confinement—in the visitors' room. Here he gets a comfortable bed with a pink eiderdown, pictures on the walls, plenty of books, the wireless, a private garden with an aviary, and three good meals a day; but no society other than that of the master whom he can summon by bell to attend to his needs. After twenty-four hours in these surroundings—scornfully dubbed "sissy" by the school at large—he is usually ready to come out and join in. And if he wants freedom on these terms he has only to ring the bell, as a notice on the wall informs him. Nor does he get shut up without plenty of warning. The headmaster explains quite clearly in advance that if he chooses to do his share like the rest he is entitled to their privileges; if he chooses not to, then he chooses the penalty as well and he, nobody else, has imposed it. Incidentally, Mr Joyce believes that official penalties, however modified, should not be abolished entirely. If there are no official penalties, he finds, you get unofficial punishments creeping in.

THE FOUNDATIONS OF SOCIAL BEHAVIOUR

The school has good games teams and plays other schools at times. Some boys who had just returned from playing a public school spoke hotly of the miserable discomfort in which their friendly hosts were living: "No chairs or backs to the seats—just forms—and no separate tables in the dining room. Nothing like as good as our place!"

Is it justifiable to place the delinquent in more agreeable surroundings than the well-behaved sons of the rich? It depends what the school can bring to the characters of the boys in it. As a rule the public school boy has behind him a secure home, and parents who have good moral standards and are capable of showing steady affection and giving sound guidance; at home he may even live a little "soft." For him school is, and probably should be, a toughening experience. Most delinquent boys have no such background of security: they come from broken homes, from scenes of family discord, or from no home at all. They have had little training in self-control, and have acquired few liberal principles. For them the school must provide the stable background which they never found at home: it must not toughen the little tough still further. While there is no "soft" living at the Cotswold school (the equipment is strong and plain as it usually needs to be in any strictly male society, whether juvenile or adult) the surroundings are beautiful, and the approach friendly. Those who do not respond to the new chance it offers them are few.

Perhaps the best tribute to the work of the school is to be found in the fact that many of the boys like to revisit it; recently five old boys came down to stay for the inter-house dramatic competition, and one even brought his wife for part of the honeymoon.

needs of the elderly A hospital car service would be needed to collect each morning's patients The department would also be a coördinating centre for the many organisations interested in the welfare of old people, and the moderate expense of setting such departments up would be offset by the advantages they offer

The prime need of old people, however, is social care medical attention takes only second place The social worker is thus a necessity in any geriatric organisation, and she can learn far more of the real needs of the person visited than the busy doctor is able to do She will also find out whether the doctor's recommendations are being carried out, and what social factors are frustrating his efforts The geriatric district nurse might also enter the picture, to carry out continuation treatment under the doctor's instruction This would ensure that the enormous numbers of elderly cardiac patients requiring mersalyl injections were given their weekly dose with the regularity which their condition demands

RECOMMENDATIONS

1 Wider knowledge of clinical geriatrics is urgently required, and this calls for more intensive practice of medicine among the aged, more careful investigation of their ailments, and more necropsy studies

2 Regional postgraduate courses in geriatrics are needed

3 An increased capitation fee should be given for patients in this age group, to compensate the general practitioner for the time spent on them, and to encourage him in the practice of geriatrics

4 Geriatric outpatient departments should be set up

5 There should be a closer liaison between general practitioner and social workers

A SCHOOL WITH A VIEW

THE forerunner of the modern approved school was the reformatory, often a forbidding place, in which work, discipline, and moral training were applied as the official remedies for badness in boys The pioneers were not far out in their ingredients these three go to the making of all good citizens, both in and out of approved schools But in the hundred years since the reformatories were started we have begun to find that the remedies are more effective, and the results more lasting, if the moral training is accepted and assimilated into the character, the discipline imposed from within, and the work done with a sense of personal achievement

The boys who arrive at the Cotswold School,[1] aged anything between thirteen and sixteen, have seldom had much moral training, and such discipline as they have known has been erratic and arbitrary Many of them don't care for work Yet over the past nine years 77% of those leaving the school have proved to be responsible people, never coming again into the hands of the police A further 10% have been brought into court for minor offences (such as riding a bicycle without a rear lamp), and only 13% have got into serious trouble Considering how late (speaking in terms of development) they come, and how short a time some of them stay, these results are surely remarkable

THE APPROACH

The change from a restless rebellious child to a reasonable and mannerly young person with a sense of responsibility is not achieved in a moment, but quite probably it begins from the moment the delinquent boy sees the school "Is this where we're going to have lunch?" one asked, as he saw what he took for a hotel lying hospitably open to the world no barbed wire, no men with guns to gratify a film fed imagination, but spacious grey buildings, some old some new, lying among gardens lawns, and playing fields in a Cotswold valley He must have felt at that moment, however obscurely, that his fellow countrymen hardly regarded him as an outcast or an enemy

There are three houses in the school, all good but all as different—Mr C A Joyce, the headmaster, finds—as the personalities of the masters in charge of them In one there is almost military precision, the boys being required to do things to time and keep strictly to the house-rules In the second they are expected to take more responsibility for their own behaviour and to work to a much less rigid time table In the third there is almost a random atmosphere, but everybody seems to be happy and at home in it The headmaster asks every new boy whether he thinks the stricter house would suit him best or one of the others, and takes his answer into account when placing him It is quite common, he finds, for a boy in one house to ask to be transferred to another

Another subject always comes up in that first conversation with the headmaster

"Oh, and by the way," he says as the boy is leaving, "if you think of running away at any time, just come and have a word with me first, will you? What are you grinning at?"

"Because you wouldn't let me go," comes the invariable reply

"I would, I couldn't stop you, anyway But if you'll come to me first I'll explain exactly what you'll be losing by it You see, you get fourteen days' holiday, but if you're away for three days without leave, you lose three of them"

This is the standard teaching about penalties "You don't *have* to have them, you bring them on yourself"

THE WAY IT IS DONE

Boys under fifteen get ordinary schooling, but with the addition of regular classes in suitable ethics ("based on Aristotle, but I don't tell them that") The older boys can learn many different trades and occupations The home farm gives them experience in milking and the care of farm animals, and there are plenty of rabbits and birds and other pets to look after Gardening is taught by a Scottish master, a personality, who puts up outspoken weekly reports on their work and character on a public board, and is both enjoyed and respected There are carpentry and engineering shops, classes in shoemaking, and a building and decorating department The teachers take pleasure and pride in their crafts, and that attitude is catching

Manners are friendly and good Boys passing each other or crossing the path of a visitor pass the time of day, and they notice and comment on any failure in manners among members of visiting schools Through the whole curriculum runs moral training, implicit and explicit The religious background is important, in the headmaster's view The boys take a large share in the services in the school chapel, and though only one service in the week is compulsory more than half the boys come to the three other services at which attendance is voluntary On weekdays evening prayers are held in the school hall When the school bell rings, at eight o'clock, there is a minute of silence, boys wherever they are in the school pause in what they are doing and stand, to observe it Afterwards they and the masters gather in the school hall, and there is a short talk, lasting three or four minutes, from the headmaster,

Perhaps the best tribute to the work of the school is to be found in the fact that many of the boys like to revisit it, recently five old boys came down to stay for the inter-house dramatic competition, and one even brought his wife for part of the honeymoon

CENTRAL HEALTH SERVICES COUNCIL

The Central Health Services Council has appointed a committee to consider "whether the existing arrangements for engaging in general practice under the National Health Service are such as to enable general medical practitioners to provide the best possible standard of service and, in particular, to advise upon (i) the range of work and standards of practice which should be expected from the general practitioner by the public and medical profession, (ii) types of general practice, (iii) mode of entry into general practice, (iv) non medical help, (v) equipment and environment, (vi) method of remuneration, (vii) liaison with hospital and specialist services, (viii) liaison with local authority services"

The members are Sir Henry Cohen, F R C P (Liverpool) (chairman), Dr G O Barber (Dunmow), Dr S C Barnes (Wirral), Mr N F Baylis (clerk, Nottingham County and City Executive Council), Dr W Russell Brain, P R C P, Dr J A Brown (Birmingham), Dr B Cardew (general secretary, Medical Practitioners Union) Dr H G Dain (Birmingham), Sir Allen Daley, F R C P (M O H, County of London), Dr E A Gregg (chairman of council, British Medical Association), Dr W V Howells (Swansea), Dr Enid Hughes (Ruthin), Alderman Mrs V F King (chairman, Southampton Executive Council), Prof Hilda Lloyd, P R C O G, Dr W N Pickles (Aysgarth), Dr A Talbot Rogers (Bromley Kent) Mr E W Scorer (member of Sheffield Regional Hospital Board), Dr Stephen Taylor (London) Dr J S Thomas (Manor Park London), Mr H P Travis (secretary, Bolton Hospital Management Committee) Sir Cecil Wakeley, P.R C S, and Dr C W Walker (Cambridge)

The secretary is Mr H N Roffey of the Ministry of Health Any person or body wishing to submit evidence the committee should in the first place give notice to Secretary, Room 358, Ministry of Health, Caxton , Tothill Street, S W 1

DINNER TO LORD HORDER

Last Saturday over 150 members of the Fellowship for Freedom in Medicine and their wives or husbands assembled at the Park Lane Hotel to pay tribute to Lord Horder on the eve of his 80th birthday The company included members who had come from all parts of England and Sir Henry Dale, F R S, read telegrams from a number of well wishers who were unable to be present Sir Henry said that, as one who was some years younger than the chief guest, and as one of his pupils, he was proud to be present on this very special occasion

Proposing the toast of the evening, "Lord Horder, good luck to him and to the Fellowship for Freedom in Medicine," Dr R Hale-White expressed the belief that however great Lord Horder's service may have been to profession and public as a consulting physician he was rendering a greater service now in his stand against the barbaric attack on Medicine When the Act became law many were horrified, some said so, a few said What can we do?, but nobody did anything much except Lord Horder Dr Hale White went on to pay tribute to the enormous amount of work that Lord Horder had done for the Fellowship, and how his wisdom had guided it Turning to the guest of the evening he said You tell me that you are 80 tomorrow In age it is not the number of years that counts, but the man. You combine the wisdom and the experience of age with a love of fun and a zest for life that many leave behind them in their teens I say you are the man, more than any other, that doctors up and down the country look to to show them a way out of the mess, and that goes for the public too It is due to the steadfastness of your actions, and to the fact that you will not tolerate any division of the profession into specialists and G P s, those inside the Act and those outside physicians and surgeons, the senior and the junior, or even the profession and the public '

Lord Horder's speech in reply was characteristic in its telling phrases and witty asides He was greatly moved by his reception

Public Health

DOES VACCINATION HELP TO SPREAD SMALLPOX?

C Killick Millard
M D, D Sc Edin
MEDICAL OFFICER OF HEALTH FOR LEICESTER, 1901–35

If I were asked in what principal respect my position as regards the vaccination question differed from orthodoxy, I think I would say In making a distinction between the effect of vaccination upon the individual and its effect upon the community When I first pointed out this distinction many years ago it was rather scoffed at The community, it was said, was made up of individuals, therefore if vaccination benefited the individual by protecting him from smallpox, it must necessarily benefit the community Nevertheless it is quite conceivable that a thing may be beneficial to the individual and yet detrimental to the community Take the analogous case of smallpox inoculation When this was introduced into this country in the 18th century, it was certainly beneficial to the individual, in that it reduced the risk of his dying from smallpox Like vaccination, it gave him a mild attack of disease in order to prevent a more severe attack later on At first it was believed to be a very real blessing, but after a time it was discovered that inoculation had a very serious drawback from the point of view of the community—it tended to spread smallpox, and often smallpox of a virulent type Ultimately it was made illegal

Now I submit that vaccination, like inoculation, has a definite tendency to spread smallpox, and (what is most important) smallpox often of a virulent type. It does this because, after its full protective effect has worn off, it mitigates an attack and is thus very apt to mask the true nature of the disease, and the modern methods of controlling smallpox (chiefly isolation and close surveillance of contacts), depend entirely for their efficacy upon prompt recognition of each case

OPINIONS FROM THE PAST

The part played by mild modified cases of smallpox which have escaped recognition—"missed" cases—has of course been long admitted Here are some expressions of opinion from medical officers of health (now deceased) who had practical experience of fighting smallpox

Dr J Niven, M O H., Manchester "It is not too much to say that by far the most important factor in the spread of smallpox in Manchester has been the over looking of cases The attack as a rule was so mild that no medical advice was sought or it was not recognised as smallpox by the medical attendant' In fact this matter is of so much importance that it is not too much to say that if there had been no case over looked there would have been practically no smallpox outbreak in Manchester' (Health Reports, 1902 and 1903)

Dr A K Chalmers, M O H, Glasgow "As in past outbreaks we are again finding that one of the greatest obstacles to effectively coping with the disease is the occurrence of an extremely mild and modified form which escapes recognition until as a result secondary cases of a graver nature arise' (Smallpox Report, 1903)

Dr W E Armstrong, M O H, Newcastle upon Tyne 'With respect to the more positive means by which the spread of smallpox has been favoured, probably the failure to recognise the disease in its mildest forms is entitled to first place A large number of localised outbreaks have been traced back to such mild unsuspected cases, where persons affected had for weeks been going about in a highly infectious state" (Smallpox Report, 1903)

It will be noted that in none of these utterances is it suggested that these mild cases, the cause of all the rouble, were difficult to recognise *just because they had* *een vaccinated some years before* Very often the fact f their having been so vaccinated is not even mentioned , ut at the time of which we are writing it was major mallpox which had to be dealt with, and in major mallpox mild modified cases such as we are considering ere almost unknown except in vaccinated subjects ometimes indeed the effect of vaccination in mitigating mallpox in these cases—so detrimental to the community -was actually hailed as a boon, as of course it was rom the point of view of the individual Thus the O.H for Carlisle wrote

> "In several instances the disease was so little marked as to escape recognition until a late period of convalescence when, as the result of the examination of all the inmates of infected houses the cases were detected Such cases were invariably associated with efficient vaccination in the persons in whom they occurred thus bearing impressive evidence of the power of vaccination in mitigating the severity of smallpox ' (Annual Report 1903)

Some medical officers did indeed recognise and admit his drawback to vaccination, but they regarded it as n argument for more rather than for less vaccination , nd there was a definite movement at that time in favour f making revaccination as well as infant vaccination ompulsory Today of course any question of compulsory evaccination has long since passed so what we have o consider now is how far this undoubted drawback to accination outweighs any advantage it may have in rotecting the community By " vaccination " is implied accination of the general population not the vaccination nd revaccination, as often as may be necessary of a andful of officials who may have to handle smallpox whenever a case may occur

And here I would give credit to Dr J H C Dalton or being the first, so far as I know to draw attention o this aspect of the vaccination question In 1893 in the *Medical Chronicle*, he wrote

> " That the community are benefited however, is a much more doubtful point It may even be urged that infant vaccination may promote rather than arrest an epidemic
>
> It has often been observed that the origin of an epidemic has been in two or three vaccinated persons who had the disease in such a mild form that it was not recognised until late Now vaccination undoubtedly causes the disease to be mild if vaccination had not been systematically performed prompt means of isolation could have been at once taken and possibly the epidemic could have been stamped out For these reasons I am inclined to doubt whether infant vaccination is such an unmixed blessing to the community that the State should enforce it with legal penalties "

Of course antivaccinists have repeatedly drawn attention to the frequency with which outbreaks of smallpox have been started by vaccinated persons, but as they have been unwilling to admit the mitigating effect of vaccination, they were unable to make use of what is, as I submit, one of the strongest of all arguments against universal vaccination of the general population

EXAMPLES

A striking example of the mischief which may be done by an unrecognised case of smallpox occurring in a vaccinated subject was the outbreak in the East End of London in 1911

Annie Levy, aged 12, *vaccinated in infancy*, living in Stepney, was taken ill with a modified attack of smallpox She went as an outpatient to the London Hospital where the case was diagnosed as chickenpox and she was sent away with a bottle of medicine Later she was admitted to the Mile End Poor Law Infirmary and placed in a ward with some 60 women and children She was seen by the medical superintendent but he too failed to recognise the real nature of the case The girl was sufficiently ill to be placed on the visiting list and was visited by her relatives and friends, also a large number of the public visited the ward and were allowed inside on visiting days

The consequences of this error in diagnosis were about as serious as they could have been 26 other inmates of the institution contracted the disease and 8 of these died , 5 nurses were attacked and 1 of these died , a scrubber who lived out and 4 of Annie Levy's brothers and sisters were also attacked In addition there were a large number of cases in persons who had visited the institution Altogether there were some 70 cases (10 fatal) directly or indirectly traceable to Annie Levy before the outbreak was stamped out As was said at the time, if we had wanted a prize method for spreading the disease and starting a widespread epidemic we could hardly have devised a better one !

Although there had been a good deal of vaccination default in the East End, the great majority of the cases which occurred in this outbreak were in vaccinated persons Thus out of the first 54 affected no less than 41 were vaccinated, 3 being in children under five years Yet the provaccinist press did not hesitate to attribute the outbreak to the neglect of vaccination Here is a sample of what one influential paper, circulating among the *intelligentsia*, wrote

> The feeling has of late been gaining ground in well informed circles that the anti vaccination campaign, and the deplorable effect it has had upon legislation, would before long lead to the re appearance of the hideous disease which vaccination had practically stamped out For years the Mile End Guardians have been anti vaccinators, discouraging vaccination in every direction The result has been that a large unprotected population has grown up and the soil has been only waiting for the seed The agitation against vaccination is one of the most idiotic things which even our sentimentalists in their record of imbecility have ever carried on

At the time this was written there had been 25 cases in the outbreak but only 2 of the patients were unvaccinated, one of these being a baby only a month old It was this sort of travesty of the truth, not at all unusual at the period of which we are writing, which made antivaccinists ' see red " , and, looking back, one can hardly be surprised that it did so

Here are some further examples

Newhaven, 1912 " This small outbreak of 26 cases originated with a seaman This man who had come back to England was attacked a week after his arrival by a mild illness with skin eruption for which no medical advice was sought Eleven out of twelve inmates of the house were attacked by smallpox, and seven other cases occurred in neighbouring dwellings whose infection could be referred to the household primarily affected Four other cases occurred later in two other households which were probably related, and four other cases in neighbouring districts which could be directly traced Of these 26 cases five proved fatal including three unvaccinated children in one household

Croydon 1918 ' A 'de mobbed' soldier, W , returned to his home from Macedonia During his journey home another soldier, supposed to be suffering from chickenpox, was removed from the truck in which W was travelling W was kept in quarantine for two weeks before being allowed to go home He did not admit to having had any symptoms But after reaching home he infected his wife and she infected their four children Five other cases were infected from these '

New Forest R D 1921 ' The infection was introduced by a seaman who returned to his home from a voyage to the East suffering from a mild and unrecognised attack of smallpox Of the nine persons in the household all with the exception of one well vaccinated child, contracted the malady and a direct contact was also infected "

In none of these reports is there any reference to the vaccinal condition of the original overlooked case which caused the outbreak , but I think we may safely assume that they had all been vaccinated and quite possibly revaccinated Revaccination is no guarantee against the occurrence of unrecognised cases

UNRECOGNISED CASES OF SMALLPOX IN THE UNVACCINATED

It may be argued that unrecognised cases of smallpox may occur in persons who have never been vaccinated, and this is true Such cases fall into two quite different categories (1) mild and trifling cases, and (2) very severe cases The mild and trifling cases very rarely occur when we are dealing with true major smallpox but only when we have to do with a mild strain of the disease, and, when this is so, *the mildness tends to breed true* Here is an example taken from my own experience in Leicester

Elizabeth C, aged 18, unvaccinated, was taken ill with a mild attack of discrete smallpox the source of which was never discovered She consulted a doctor, but he mistook the case for one of chickenpox and no precautions were taken The result was that she infected all the 9 members of her household, 6 employees at the factory where she worked, and 4 persons outside, also one of her sisters carried the infection to her Sunday school where a teacher and 5 scholars were attacked 25 persons in all But *only 1* of the 25 cases proved fatal How different would have been the result if the mild infecting case, Elizabeth C, had been suffering from a severe strain of smallpox made artificially mild by vaccination!

In the second category of unrecognised cases in unvaccinated subjects, the disease is of a very severe type, and the illness may be mistaken for measles or other zymotic, purpura, or some form of toxæmia Dr C O Stallybrass in the *Medical Officer*, of July 29 last, mentions for example the *Tuscania* outbreak of 1929, with 35 cases and 11 deaths, in which the unrecognised case was ascribed to "purpura" Of this the Chief Medical Officer to the Ministry of Health, in his annual report for 1929, wrote

> These cases presented an entirely different clinical picture from that to which the public has lately been accustomed They are marked by profound prostration, hæmorrhage into the skin and a confluent eruption The disease is so severe from the outset that medical aid is at once sought the patient is confined to bed and thereby the number of contacts is reduced to a minimum "

Dr Stallybrass thinks that the danger of spread from unrecognised cases in unvaccinated subjects counterbalances my argument as to the danger of spread from unrecognised cases in the vaccinated I am sorry I cannot agree But Dr Stallybrass has had such a great experience in dealing with smallpox that his opinion must necessarily command great respect I can only leave it therefore for others to decide I would merely point out that the outbreaks he quotes are very exceptional (he includes one from Canada), that the patients are not ambulant or only ambulant for a very short time, that they are so ill that a doctor must necessarily be called in, and that they have generally been persons recently arrived home from the East It ought not to be too much to expect of doctors that in such cases resembling measles, purpura, or toxæmia, with the patient seriously ill, they should bear in mind the possibility of malignant smallpox

Incidentally I am all in favour of every one who visits the East being efficiently protected by recent vaccination, just as I am in favour of their being inoculated against other Oriental diseases, but I do not think it necessary that we at home should all be inoculated against those diseases

WHAT TYPE OF CASE IS MOST INFECTIOUS

It is often supposed that a severe case, seriously ill, with a profuse eruption fully developed, must give off more "infectious material" than a slight trivial case, hardly ill at all, and with only a very sparse eruption I am not aware, however, that there is any very definite evidence to support this view The fact is we have little knowledge of the conditions under which infection is given off from one individual or is transmitted to another Often when we expect the disease to spread it does not do so, and vice versa We are quite in the dark as to why this should be Let me give one of several examples from my own experience where much greater spread might have been expected

R W, a tailor by trade, tramped from London and took lodgings in Leicester He was taken ill the day after his arrival Three days later the eruption appeared and he then went as an outpatient to the Royal Infirmary sitting in the waiting room amongst a number of other patients Unfortunately the nature of his illness was not recognised The same afternoon he visited one of the most frequented drinking bars in the town The following day (Sunday) he stayed in all day but the next day he again visited a public house The man was now so ill and the eruption so obvious that the publican's suspicions were aroused and he sent word to the Health Office Meanwhile, however, the occupier of the house where he was lodging had also become suspicious and called in a doctor who at once reported the case and he was then removed to hospital The attack proved to be a very severe one, of the hæmorrhagic type, which proved fatal three days after admission Here again we naturally expected that further cases would arise, but not a single further case resulted

As a contrast let us consider the comparatively recent outbreak of virulent smallpox at Glasgow Here, an Asian seaman, Moosa Ali, "well vaccinated," recently arrived in this country from the Far East, developed an attack of smallpox As the event proved it was major smallpox, but so mild and modified by his previous "good" vaccination that the experts decided, after careful consideration, that it was chickenpox and no proper precautions were taken The result was most disastrous During the short time he was in hospital he infected no less than 18 other persons in, or in connection with, the institution, and 6 of these died This case, in spite of being clinically so slight, must indeed have been highly infectious

THE ROYAL COMMISSION ON VACCINATION

The most authoritative and exhaustive inquiry ever made into vaccination was the Royal Commission, and by the very first term of their reference it was instructed to inquire and report as to (1) "the effect of vaccination in reducing the prevalence of and mortality from smallpox,"—in other words, the effect of vaccination in *protecting the community* Yet after seven years' deliberation the commissioners never answered this question at all What they did was to express their opinion as to the effect of vaccination *upon the individual* nothing whatever is said as to its effect upon the community—i e, in reducing the prevalence of and mortality from smallpox In view of all the claims, so often and so confidently made, as to the great reduction in smallpox prevalence and mortality which vaccination was supposed to have effected since its introduction at the beginning of the 19th century, this omission is certainly most surprising

The fact is of course that it is in its effect in protecting the community that the case for vaccination is weakest, and it is here that the antivaccinists have, in my opinion, much the best of the argument and have scored their strongest points As regards the effect upon the individual the provaccinist case is almost impregnable—except that the duration and extent of the protection conferred has been greatly overestimated—and it is because the antivaccinists refuse to recognise the effect of vaccination upon the individual that they have failed to make any real progress in winning over scientific opinion

THE LATEST ARGUMENT FOR INFANT VACCINATION

Some medical officers of health are now advocating universal vaccination in infancy on the ground that there is apparently less risk of postvaccinal encephalitis if primary vaccination is done early in life As many people have to be vaccinated sooner or later—e g when going out to the East or if they join the Services—it is better (for the individual) to have this done in infancy There may be something in this argument , indeed, it is perhaps the strongest that can be used today, though if it were frankly put before parents its propaganda value would be doubtful But what a different argument from that originally used—namely, that unvaccinated persons were a danger to the community !

MAY INFANT VACCINATION INCREASE THE VIRULENCE OF THE "STRAIN" OF SMALLPOX ?

Antivaccinists have frequently pointed out that in the official statistics of a smallpox epidemic the case mortality in the unvaccinated group—which is nearly always much higher than in the vaccinated group—is greater (say, 15–30%) than was the estimated case mortality in prevaccination times (say, 5–15%) when all were unvaccinated I am inclined to agree with them in this, though I do not agree when they go on to contend that this is evidence that the official statistics of smallpox epidemics are not to be trusted I think that there is a possible alternative explanation—namely, that infant vaccination may tend to increase the severity of the "strain" of the disease

What has been said above indicates how this might come about We have seen that smallpox is chiefly spread by clinically trivial ambulant cases rather than by severe bedridden cases , also that mild cases in unvaccinated subjects tend to transmit their mildness (to "breed true") and therefore spread a mild strain of the disease whereas mild cases in vaccinated subjects —where the mildness is merely due to the fact that they have been previously vaccinated—often transmit a highly virulent strain Assuming that this tendency is always at work, it is easy to understand how the "strain" of the disease might in the course of time become permanently more virulent than would have been the case in an unvaccinated population Persons protected by vaccination would still get the disease in a much milder and less fatal form, but those who were unvaccinated, and also those whose vaccination had lapsed, would get it in a more severe form , so the net result might well be that the total mortality was just as great as, or even greater than, if there had been no vaccination It would all depend upon the relative proportion of the two classes in the population how it would work out If there were a large proportion of unvaccinated, or of those vaccinated who were no longer protected the mortality might actually be higher This may possibly explain why it is very uncertain just what effect vaccination has had in reducing the mortality from smallpox—i.e , its effect upon the community

The belief, so long and so firmly held, that the great reduction in smallpox mortality which followed the discovery of vaccination was due to vaccination is no longer tenable, seeing that the fall began before the introduction of vaccination and has continued steadily in spite of vaccination having largely fallen into disuse Moreover it is paralleled by a similar fall in the mortality from several other zymotics

THE CASE OF INDIA

One hesitates to refer to India, without having personal experience of that country and its problems But it is common knowledge that the toll of human life taken by smallpox in India (tens of thousands of deaths annually) continues to be appalling in spite of all efforts to combat it by vaccination, a vast amount of which is carried out The immediate cause of this great mortality is the intense virulence of the disease, which is such that only very recent vaccination will stand up against it (British troops in India had to be revaccinated every two years, which of course would be quite impracticable for the general population) One may try to explain this exceptional virulence as due to climatic conditions, the habits of the population, or neglect of hygiene but it is hard to believe that the virulence could have been as intense in prevaccination times, or the people would have been wiped out The suspicion therefore rises, and should be faced that in India, as in this country, though vaccination saves many individual lives, it may have actually made things worse for the community by intensifying the severity of the disease

I am not suggesting that India should now abandon the use of vaccination But I do think that it might be worth trying the experiment of introducing, on a sufficiently large scale, a very mild form of smallpox such as variola minor (alastrim) from the Western Hemisphere This could do no harm, and if it could be persuaded to "catch on" it might transform the entire situation More wonderful things have been successfully accomplished in the field of botany and agriculture The difficulty would be getting it to "catch on," but this might be done if inoculation with variola minor took the place of inoculation with vaccinia (vaccination) The experiment might be made in the first place in one town or district The present position is so serious that much more heroic measures than this would be justified

SUMMARY

The effect of vaccination upon the community must be distinguished from its effect upon the individual By masking the disease and making it more difficult to recognise, it may actually promote the spread of smallpox

Infant vaccination may conceivably have intensified the virulence of the "strain" of smallpox, both in this country and in India The mortality from smallpox in India might possibly be reduced by deliberately introducing a milder strain of the disease

---

Influenza

The statistics for England and Wales and the Great Towns do not indicate any serious epidemic of influenza up to the end of last year Any increases in pneumonia cases and deaths and in influenza deaths are not much more than normal for the time of year

A mild form of influenza, but of a very infectious type, has been epidemic in the North-east of the country including Newcastle upon Tyne, in parts of Lancashire including Liverpool, and in Birkenhead (Cheshire) The evidence is, however, that in these districts the epidemic has passed its peak and is on the downgrade. Serological investigations have now shown that the epidemic in Tyneside is due to virus A, and it may well be that it is identical with that which has been the cause of the Scandinavian outbreaks—virus A prime The results of further laboratory investigations are awaited

There is at present no evidence of spread of the epidemic to the Midlands and South There are, however, in many areas localised outbreaks of a mild disease with symptoms not unlike those of influenza, which has not so far been shown to be due to an influenza virus There is similarly no evidence of spread of the epidemic from the North to London

In the absence of notification of influenza the incidence of pneumonia cases and of deaths from pneumonia and influenza is used as a guide to the prevalence of the disease The following figures relate to the great towns of England and Wales

Week ended Dec.	*Pneumonia (including primary and influenzal)* *Cases*	*Deaths*	*Influenza deaths*
16	374	289	33
23	364	351	54
30	502	383	102

In England and Wales notifications of pneumonia numbered 686 in the week ended Dec 16, 648 in the week ended Dec 23, and 962 in the week ended Dec. 30

Smallpox at Brighton

Up to noon on Jan 9 there have been 17 patients believed to be suffering from smallpox in Brighton county borough, or in the immediate vicinity Of these, 2 have died and the diagnosis is still in question in 3 During the past week, the infection has been confined to the two original foci—the laundry to which the clothing of the initial case, an R A F officer, was sent, and the hospital in which the second case was missed for ten days

Among the laundry employees there have been 6 cases 2 worked at a receiving branch and the remainder in the main establishment The laundry is now out of production The hospital is in quarantine, and of its personnel 5 nurses and 1 domestic have been admitted to the smallpox hospital All these were employed on the ward to which the second case was admitted and nursed in a cubicle

The vaccinal state of the nursing and domestic staff at the infectious disease hospital was unsatisfactory, 27 out of 113 had never been vaccinated Among the nurses and domestics attached to the ward concerned 7 were unvaccinated Of these 3 had little contact with the patient, and did not get the disease, of the other 4, who had intimate contact, 1 died and 3 are in a serious condition The remaining 2 nurses now in the smallpox hospital have a good vaccinal history and there is still some doubt as to the diagnosis

Poliomyelitis

Poliomyelitis notifications in the last week of the year were paralytic 36 (38), non-paralytic 17 (15), total 53 (53) The figures for the previous week are in parentheses and the total number of notifications was the same in each week Total uncorrected notifications for 1950 are 5698 compared with 9195 in 1947, 2379 in 1948, and 6857 in 1949 The incidence of poliomyelitis in 1950 after correction of notifications is hardly likely to be much less than that in 1947, when it was $4^1/_2$ times greater than in any previous year since compulsory notifications began in 1912

The Third Quarter in Scotland

In Scotland [1] during the third quarter of 1950 the death-rate from all forms of tuberculosis was 43 per 100,000, and the death-rate from respiratory tuberculosis 37 per 100,000 These rates are 16 and 14 below those for the corresponding quarter of 1949, and they are 22 and 17 below the five years' average

In the third quarter the infant mortality rate—33 per 1000 registered live births—was the lowest recorded in Scotland for any quarter

In England Now

A Running Commentary by Peripatetic Correspondents

WHEN my friend Tom was in the Army they discovered he had a chronic illness that would make it difficult for him to practise medicine He could not contemplate the strains and irregular hours of a G.P's work, so he joined the staff of an L C C mental hospital He is a competent doctor and a very kindly man, and he soon settled down to the undramatic and rather thankless task of making life a little less unpleasant for chronic psychotics. He took the D P M, bought a house near the hospital, and moved in with his several young children In 1948 they told him that he was to become a trainee specialist instead of an assistant medical officer "Don't want to be any more of a specialist than I am now," grumbled Tom When he was metamorphosed into a registrar he merely shrugged his shoulders Now they tell him that he must leave in the summer "Why?" asks Tom, truculently "Because you can't become a consultant," says the R H B "Don't want to be a consultant," growls Tom, "never did" "Good!" says the R H.B., "you are one of the lucky ones You can go to the Colonies with a good grace"

Tom is a bit of a Tory and I had had a hard job persuading him that the N H S was a good idea Now I can't look him in the eye at all

* * *

It is a dangerous habit, this skimming through the Tables of Contents of the journals or glancing at the titles of the articles, and then laying them aside as read. The other week, for instance, I was idly turning the pages of THE LANCET when the words "Milkman's Syndrome" caught my eye Underneath the title was this quotation "At times the bowel complaint is overlooked the wasting, weakness, paleness are what is noticed, and are thought to be due to another than the true cause" Hmm, I thought, curiously enough our milkman is wasted, weak, and pale For all I know he may well have "the bowel complaint," but as long as it's not typhoid My thoughts rambled on No wonder the poor fellows get wasted, weak, and pale, having to be out and about at some ghastly hour on these cold mornings I wondered whether the syndrome had a psychiatric component Our milkman certainly seems manic depressive—manic when asking for his money and depressed when he doesn't get it But what's this? Ye gods! Further down milkman has a capital M And his syndrome turns out to be "Multiple Spontaneous Idiopathic Symmetrical Pseudofractures" Curse these eponymous titles! But I suppose the author couldn't very well call his paper "Multiple Spontaneous Idiopathic Symmetrical Pseudofractures in Idiopathic Steatorrhœa Complicated by Refractory Macrocytic Anæmia"—he might have brought the compositors out on strike again

* * *

Even a smallpox scare—or should I say a vaccination epidemic?—has its lighter side Vaccinating contacts on New Year's Eve we found their main fear, apart from anxiety lest they spread the disease, was centred round the cocktail cabinet "This doesn't stop us drinking does it, Doc?" Small boys thrilled at the prospect of no baths, and some mothers, very much under their influence, began to think the whole thing a plot to save fuel

How different were these jolly folk from the panicky public who, for four days, rang our telephone bell on an average every seven minutes with urgent messages for the doctor to "Come and vaccinate me at once My cousin shook hands with the uncle of an ambulance man" or "I've not been out of the house for the past three months so must be specially liable to infection" Many patients refused to attend clinic or surgery on the grounds that they might catch the disease while awaiting vaccination It is difficult to keep one's temper from 8 A M until 10 P M, particularly with such patients as the woman who looked round our spotless waiting room and said 'When I come to have my ears syringed I don t expect to be exposed to contacts" To the best of my knowledge there was no contact in the place My halo slipped half-circle and I told her there was nothing between her and the front door She did not take the hint, but, sunk in sables, brooded in a corner while the other patients did their best to give her the creeps

On reflection, I suppose we should be grateful to the cringing souls who preferred a guinea's worth of lymph in their own homes to State benefit in clinic and surgery, but what a pest they are in emergency

Our hopes that people would stop calling the doctor to their homes for colds because we might infect them with smallpox were short-lived The telephone engineers scored instead One who gave new life to our jaded phone told us that he had been refused entry because it was known that postal authorities had had some contact One facetious patient, looking round our five-bob a nob clinic remarked "You'll be able to retire after this" Somewhat bitterly we replied "No doubt—to the nearest asylum"

As wife and general factotum, my saddest moment came when my husband returned from vaccinating the Golden Goose in the local pantomime He was empty-handed Even an ordinary egg would have been welcomed

I must leave you now and take our temperatures My husband is looking for a rose petal under the mattress I've a nasty feeling that the M O H will have to be informed

* * *

It was my first morning as a teacher of practical anæsthetics at this Scandinavian hospital, so my ignorance of the operating theatre lay out was excusable I arrived at 7 A.M and I had been told that operating usually went on until 2 in the afternoon I undressed in a bare room resembling the steam room of a turkish bath on closing day, and put on the usual shapeless trousers, topped by a rather bedraggled collarless limp coat —gowns, it seemed, were not worn by porters, visitors, or anæsthetists Clogs were provided as footwear and I soon discovered why The theatre floors were kept continually covered with a half inch layer of acrid ammoniacal disinfectant solution in which everybody sloshed about As the morning wore on, the three or four cups of coffee I had drunk before dressing at the unholy hour of 6 A M began to take effect, and the time came when, with an intravesical pressure well-nigh unbearable, I had to teeter out of the theatre on my clogs to seek relief By now my feet felt like a Chinese maiden's, and the clogs seemed to have increased enormously in weight I stumbled along the corridor trying various doors, but none was the one I wanted Oddly enough, though everybody in the town seemed to speak and understand English well when one asked the way or wanted a tram ticket, here I found it was impossible to make myself understood I tried every variety of accent on the words that I felt sure must be of international significance, but "toilette" and "lavatoire" produced no signs of comprehension in the nurses I accosted At last my efforts were rewarded —by a cleaner who it later appeared had scrubbed for a time in Britain. Arriving with my last gasp at the door she had indicated I was about to enter when a grim secretarial lady came across the corridor and told me in clear and authoritative English "You cannot go in there, *that* is the Professor's lavatory!" Needless to say I committed the unforgivable and entered the unenterable I do not know whether the Professor heard about this lapse or my subsequent ones, but it may be significant that throughout the week I stayed at his hospital he never once said "Good morning"

* * *

Despite the ice-bound roads our bank manager rode the six miles to and fro between his home and the bank every day on his autocycle He is a large man who spends a goodly part of each day in the local One afternoon he set off home clutching a bottle of brandy, skidded, and fell, damaging the bike and dislocating his shoulder, but caring for none of it because he had saved the brandy He was not seriously perturbed by an uncomfortable night, the 15 mile journey to hospital for X ray, or having his shoulder reduced But he returned home ready for the solace of his hard-earned bottle Alas, his wife had knocked it off the kitchen table

Letters to the Editor

TREATMENT OF PERFORATED PEPTIC ULCER

SIR,—I should like to reply to some of the points raised in your leading article of Jan 6 As you say, when assessing the results of a non operative régime it must be remembered that in a proportion of the cases proof of perforation is lacking In the series reported from King George Hospital, Ilford, however, there is some circumstantial evidence that the figures have not been significantly "padded" by the inadvertent inclusion of cases other than perforations Of the 73 cases that Mr Hermon Taylor reports, 68 were examined radiographically and 65 4% showed subphrenic gas This corresponds with the experience of McElhinney and Zinniger,[1] who found subphrenic gas radiographically in 65% of 122 patients in whom the diagnosis of perforation was proved at operation Of the remaining 5 patients in the King George Hospital series, 4 had the diagnosis established at operation

No strict controls are available for the King George Hospital cases, but they may be compared with records on the same basis from Guy's Hospital and the London Hospital The results are remarkably similar

	Guy's 1946–49	*London 1946–49*	*King George 1946–50*
No of patients	75	75	73
Perforations sutured	69	65	6
Treated by aspiration only	4	7	65
Total deaths	7	10	7

Surely neither Mr Hermon Taylor nor Mr Stead suggests that gastric aspiration should be considered a rival treatment to operation Rather does their work help towards a better understanding of the therapeutic value and dangers associated with these two measures The conception of "the single final stopping of the leak which only operation can secure," and reliance on operative "closure" alone without efficient gastric decompression, still lead to tragedies from persistent leakage As Roscoe Graham[2] pointed out in his classic paper fibrin and fibrosis produce the real closure, operation can only provide the scaffolding Baritell,[3] reporting a series of 88 operations with 1 death, stressed the importance of gastric suction and stated that "watertight closure is entirely unnecessary" McElhinney and Zinniger[1] report 128 cases with 8 deaths and they also emphasise the importance of combining gastric suction with operation

Reports of this type, taken together with the results obtained when operation is omitted, may incline opinion to the view that operation is an important accessory in treatment, to be used for increasing the safety factor after this has been balanced against the added risks

Wallington Surrey JOHN F R BENTLEY

CORONARY DISEASE AND MODERN STRESS

SIR,—As Professor Platt points out, the evidence for an especially high incidence of coronary thrombosis among the medical profession is rather shaky, but even if such a preponderance were conceded, the jump from this fact to the conclusion that special psychological stresses play an ætiological rôle is so far as to make it of interest to examine the reasons for this prevalent notion

The play of human emotions is often associated with certain precordial sensations which, for the sake of brevity, we might refer to as pangs Pangs have been a powerful influence in shaping the lay concepts of psychology throughout the ages, concepts which have become enshrined in all languages in expressions such as heartless, disheartened, and heartbreaking Pangs have also had their influence upon medicine Thought processes being rarely devoid of emotional content, the heart was at one time thought to be the main sensorium, and the brain was relegated to the rôle of a cooling sponge Again, in more recent times, we have learned to recognise a neurotic condition based on the misinterpretation of these thoracic sensations—the effort syndrome The "modern stress" theory of coronary disease seems to be founded on the same naïve conjectures, having not a shred of factual evidence to support it We seem to be dealing here with a sublimated form of Da Costa's syndrome medical theorists, too well informed to be able to convert the pangs into a private heart disease for themselves, are driven to make them into an ætiological hypothesis

---

[1] McElhinney W T Zinniger M M *Arch Surg* 1950 61 758
[2] Graham R R *Surg Gynec Obstet* 1937 64, 235
[3] Baritell A La M. *Surgery* 1947 21 25

Dr Macdonald Stewart's article bears signs suggestive of this Having ably shown the fallacies of the "modern stress" theory in the first part of his essay, he yet cannot avoid plumping into the pitfall he himself has so well demarcated The way in which he outlines the superior moral attitude proper to the prospective victim of coronary thrombosis and contrasts it with the low mentality of the "resentful and idle" majority suggests a hidden personal concern

In the time of our forefathers, gout was reputed to be the doctors' disease but being less hypocritical than our age they frankly attributed it to excessive tippling and not to superior mentality, although Sydenham could not forbear consoling himself with the observation that more wise men died of it than fools

Admittedly the question of coronary reactions to emotional stress and their possible chronic effects is both a legitimate and important one, but the only hopeful approach to it is by the methods of the physiological laboratory and not by pseudo psychological speculation

ERICH GEIRINGER

SOURCE OF DEOXYRIBONUCLEOPROTEIN FIBRILS IN PURULENT EXUDATES

SIR,—I was interested in the article of Dec 9 by Dr Armstrong and Dr White, and in your leading article of Dec 16 The liquefaction of viscous purulent exudates by deoxyribonuclease, streptokinase, and other enzymes looks as if it may become a valuable therapeutic procedure It may prove important to understand clearly the cytological changes which lead to the production of fibres of nucleic acid in such material

The tough viscous web in sputum and other purulent material usually follows a complex series of changes in the eosinophil or neutrophil leucocytes Responding to certain stimuli these cells eject long processes—filopodia—which may travel for as much as 200 µ in a single direction or in several different directions simultaneously They are tipped by one or more of the refractile cytoplasmic granules and are at first extremely slender and difficult to find in the unstained specimen In the earlier stages they may be withdrawn into the cell, but more often they reach their objective and the contents of the leucocyte are, as it were, poured down them, the nucleus participating in the activity and becoming filiform The cell becomes converted into a simple or branched thread

By this means neutrophils and eosinophils traverse considerable distances and, becoming attached to their objective, often draw themselves up to it so that they adhere closely to or surround the object Epithelial cells and dead or moribund leucocytes seem to stimulate this activity very strongly, whereas red cells appear to exert no positive tropism When the filopodium abuts upon any object it tends to run round it, probably led to do so by the surface pressures, for leucocytes can be seen in this way to embrace with equal facility an epithelial cell or an air bubble, and in preparations stained with Romanowsky stains epithelial cells may often be seen with blue cytoplasm and purple nucleus, and round them, like a tyre round a wheel, is applied the filiform nucleus of a leucocyte stained deeply purple

In some types of purulent material this filopodial activity of the leucocytes is responsible for arranging the familiar spherical leucocytes into long ranks lying between the filiform extensions of the more active cells If the material is not too thickly filled with cells, these ranks will ultimately be rolled up into a clump by the filopodia and undergo fairly rapid cytolysis

This is a brief and incomplete account of a few only of the activities of pus cells, but it will be realised that in such exudates the cells conforming to the classical description of leucocytes are often dead or moribund, whereas the living cells in a state of high activity are rendered unlike the classical description because of their filopodial changes In the article by Armstrong and White, for example, the figure "*b*" in each of the three series of photographs probably shows a preponderance of dead cells

The ejection of filopodia and some other activities of leucocytes have escaped the attention which they merit, and one hopes that this new therapeutic procedure will stimulate more interest in them In unstained material the activities are seen more readily in the eosinophil because of the higher refringence of its cytoplasm than in the neutrophil

The accompanying photographs show examples of the filopodial activity described above

WELFARE OF THE BLIND

SIR,—May we draw attention to the course that newly blinded people should follow if they wish to take full advantage of the blind welfare services ?

If a person's loss of sight has been caused or aggravated by war service (including civil defence), he or she should get in touch with St Dunstan's, 191, Marylebone Road, London, N W 1, which is responsible for such cases

Responsibility for all those whose loss of sight is not attributable to war service—that is, the civilian blind—is borne by the local authorities and the local voluntary agencies for the blind, in coöperation with the National Institute for the Blind Newly blinded civilians should therefore get in touch with the local blind welfare authority or, should there be any doubt as to the identity of that body, with the National Institute for the Blind, 224, Great Portland Street, London W 1, which gladly provides applicants with any information or advice they may require

W ASKEW
Secretary St Dunstan s

J C COLLIGAN
Secretary General
National Institute for the Blind

STUDY OF DELINQUENCY

SIR,—There are few greater attractions to the spectator than a good quarrel , and if Dr Bodman, Dr Edelston, and myself have only succeeded in bruising each other, we must at least have endeared ourselves, for the entertainment we have afforded, to your readers For when specialists in emotional health come to blows, who can help shouting " A ring, a ring ! "

After honourable war, honourable peace ! Peace treaties are I know not much in fashion nowadays , but who should be better able to resolve conflicts than the present protagonists ? And so it occurred to me to draft a treaty, by clauses, to place on record the highest common factor of agreement

This pacific overture is made, however, in the hope that Dr Edelston will not misconstrue it as battle weariness , it was really very ungenerous of him to take advantage of my chivalrous admission of the leading part that psychiatrists had played in the development of the new personality psychology (A bad beginning that, to peace negotiations I must make some other overture)

Dr Edelston bids me direct my guns upon my fellow psychologists Yes, there is much I could criticise in our own academic training, but actually there is no need More eminent psychologists than I are doing this already " Too many professional psychologists," writes Professor Vernon,[1] " in this country as well as in America, become *too* exclusively rat experts, or statisticians, or gadgeteers " How's that for blowing our own brains out ?

With that preamble of recrimination and appeasement I proceed now to the clauses of our treaty, as follows

1 All those constantly in touch with children and families —teachers general practitioners school medical officers and nurses welfare and probation officers—should be encouraged to detect maladjustment or unadjustment at its earliest stage (in so far as they are not doing so already)

2 The overcoming of the present tendency among such towards extreme pro or anti psychological psychiatric bias, regarding us alternatively as witch-doctors or nitwits , and a clearer understanding of the bearing of emotional health upon physical health education, and good behaviour

3 A thoroughgoing, yet realistic, training for clinicians of all types—to embrace whatever is relevant in our present medical and psychological teaching

4 Our conception of treatment to be widened to include as much as possible of the patient s life situation , and especially to do our best to see that every young person is firmly anchored in a family " belonging group," at best with his own parents, but otherwise with permanent parent substitutes (Not always easy, I confess again)

5 That in every case of delinquent breakdown, some one or other should be continuously responsible for the process of rehabilitation using whatever treatment, clinical or otherwise, is appropriate The position of a specialist who, with inadequate time and resources, has to give an opinion on a case which forthwith passes out of his hands can be a false one (*vide* Dr Peter Scott's letter of Dec 30)

Redhill Surrey

MEDICAL SCHEME FOR BOYS' CLUBS

SIR,—May I through your columns issue an appeal ? The London Federation of Boys' Clubs is about to launch a medical scheme by which regular routine medical inspection is to be offered to club members It has been found that much good comes of these examinations For this scheme to work we need doctors who will take part voluntarily in the club life for a minimum of about two hours in an evening every three weeks There are many other ways in which such doctors can help the many clubs in London , and these, together with details of the scheme, are outlined in a booklet which will be sent to any doctor asking for one Younger doctors on the house staffs of London hospitals are just as welcome as practitioners living near a particular club

It is hoped to issue a standard card for recording the results of medical inspections and it is felt that in time these might be of great medical and statistical value The scheme is to be in no sense a " sick parade," but a series of routine medical inspections , and the boys' own doctors under the N H S are never to be " by-passed " or made redundant No-one expects these busy practitioners to carry out routine inspections on apparently healthy adolescents and when any lesion is detected they will always be approached

FRANK FALKNER
Hon medical adviser
London Federation of Boys' Clubs

MASS RADIOGRAPHY

SIR,—Your leading article of Dec 9 and the divers views expressed in the ensuing correspondence show that this is not the time for regional boards, or anyone else, to make a final decision about either the scope of mass radiography or the medical direction of this new diagnostic weapon

When mass radiography was first made available for civilians, it was said that eventually every man, woman, and child in Britain could be X rayed Dr James Brailsford was the first to show that this was impracticable Since the whole population cannot be X rayed, it is obvious that mass radiography should be reserved for those groups whose survey is most likely to benefit the community Therefore, the primary aim of mass radiography should be the detection of unsuspected cases of pulmonary tuberculosis not only in the most vulnerable age and occupational groups of the population, but also among those who, by reason of their calling, are most likely to disseminate widespread infection Mass radiography is thus related both to clinical and to preventive medicine For example, to discover one case of open pulmonary tuberculosis in a school teacher it would be worth while to survey many thousands, because the removal of that source of infection would eventually save the State many thousands of pounds There would also be a saving in suffering and sorrow which cannot be assessed in terms of ducats

From the groups enumerated in your leading article I would exclude " prospective employees whose employers wish them to be examined " Mass radiography is part of the National Health Service, and the Terms and Conditions of Service of Hospital Medical and Dental Staff (England and Wales), issued by the Ministry of Health on June 7, 1949, excludes from work within the scope of the National Health Service "examinations and reports required by employers (including Government Departments and local authorities) on employees or prospective employees"

---

[1] *Brit J educat Psychol* November 1950

The average cost of finding a new case of pulmonary tuberculosis is greatly reduced when "doctors' cases," where the incidence of tuberculosis is highest, are included in the routine work of a mass radiography unit By including these cases, the unit is not competing with the tuberculosis dispensaries Every doctor is advised that all suspected cases of pulmonary tuberculosis should be referred direct to the tuberculosis officer, but he is also told that mass radiography is available for those cases in which he wishes to exclude the possibility of tuberculosis before making a diagnosis Thus a diagnosis of gastric ulcer may be right nine times out of ten, but the tenth case may be acid dyspepsia associated with pulmonary tuberculosis Those of us who have established a mass radiography service for general practitioners have been amazed by the response General practitioners say that it is easier to induce their patients to attend a mass radiography unit than a tuberculosis dispensary or chest clinic with the stigma of tuberculosis Nevertheless, when a firm diagnosis of tuberculosis has been made by a mass radiography unit, there is little difficulty in inducing these patients to attend the tuberculosis dispensary in order that they may receive appropriate treatment This assumes that the mass radiography unit is fully diagnostic to the limits of its capacity Within the scope of mass radiography are all serious chest diseases, and in "doctors' cases" a relatively large number of neoplasms will be discovered in the operable stage

The value of surveying school leavers is now generally recognised, but our target should be an annual survey of all males and females between the age of 15 and 25 On the other hand, it is most difficult to induce adolescents, other than those in factories, to be surveyed after they have left school In Birmingham we attempted to arrange an annual survey through youth organisations, but the results were not impressive

Dr Hoffstaedt, in his article of Dec 9, has shown that mass radiography may be a most expensive diagnostic weapon Before it is abandoned or curtailed on that account, the cost of equipment and of film might be referred to the commission now concerned with monopolies and restrictive practices in industry It is certainly the duty of medical directors to scrutinise all accounts and to eliminate all unnecessary expenses Dr Evans and Dr Posner (Dec 23) say

> 'If it were wished to really cheapen this service, the following action would be necessary
>
> The service would have to be regarded purely as a sieve for pulmonary tuberculosis taking miniature films and repeat films of 4 × 5 in size The staff could then be reduced to radiographer assistant radiographer, dark room technician, and two clerks, clerical work would be cut down to an irreducible minimum and all cases immediately referred to a chest clinic The post of medical director would be abandoned, and a consultant chest physician would attend for two or three half sessions per week to read the miniature and large films All surveys would be arranged by a secretary under the direction of the consultant chest physician '

In reply to this suggestion, I submit that there would be no real saving but possibly an increase in expenditure If the number of clerks in a mass radiography unit was reduced from 6 to 2, the redundant 4 clerks would be required to do precisely the same work at a chest clinic If the post of medical director were abolished, his work would have to be done by an equally well qualified and well-paid chest physician, the only difference being that films would be read at the mass radiography unit and clinical work would be done at the chest clinic If all surveys were arranged by a secretary under the direction of the chest physician, this secretary would require special qualifications to enable him (*a*) to address meetings of up to 2000 employees at a factory, (*b*) to confer with joint production committees, (*c*) to meet industrialists, and (*d*) to compose the printed propaganda for his unit In most units all these duties have hitherto been performed by the medical director An adequate substitute would require an adequate salary Moreover, it is very doubtful if any layman could supervise and control the work of professional radiographers, or whether the latter would willingly agree to this

There are two claimants for the medical direction of mass radiography The majority of tuberculosis officers would like mass radiography units, as an integral part of the *tuberculosis* service, to be attached to tuberculosis dispensaries or to chest clinics The majority of medical directors would like these units to be an interdependent integral part of the *chest* service, and as such to work in close cooperation with tuberculosis dispensaries, chest clinics, thoracic units, general hospitals, school medical officers, M O H s, and, above all, general practitioners. Some inexperienced persons have suggested that the work of a mass radiography unit is so uninteresting that no one would want to be its medical director for more than a year Having had experience of all kinds of tuberculosis institutions from an open air school to a home for advanced cases, I can testify that in none of these is the work more interesting or more varied than that of a mass radiography unit, provided the latter is diagnostic to the limits of its capacity

HALLIDAY SUTHERLAND
Medical director, Birmingham Mass Radiography Unit and chairman of the Standing Committee of Medical Directors of Mass Radiography Units in England and Wales

TYPHOID FEVER IN A GENERAL HOSPITAL

SIR,—Dr Dewar (Dec 30) will doubtless be completely satisfied with my explanation that the case of subacute bacterial endocarditis, reported by Dr Curtin in your issue of Dec 16, was admitted to Sheriff Hill Infectious Diseases Hospital for investigation of suspected acute tuberculosis of the lungs in late pregnancy

It is necessary, however, to stress the vast difference between the treatment of a typhoid case in a general hospital, with the attendant risk of infection of the nursing staff and the other patients, and the care of a non infectious condition in an isolation hospital, where the patient can be segregated in a side ward or cubicle and efficiently safeguarded from the other infectious patients

A subordinate motive for my original letter of criticism was concerned with the long waiting lists for admission to the general medical wards This factor makes it still less desirable that a patient with a notifiable infectious disease should occupy a bed in a general hospital for a long time, when he could quite well have been treated in a fever hospital In my submission, it is a very regrettable tendency to admit notifiable infectious diseases to general hospitals, where the clinical approach is mainly curative, in contrast to the combined preventive and therapeutic outlook expressed in the fever hospital

I have long held the view that the modern infectious diseases hospital should not restrict its scope to the notifiable diseases, but, subject to the limits of the available accommodation and the facilities for treatment, should also accept for investigation and treatment any condition in which microbic infection is suspected or proven This would cover the throat infections, the pneumonias, the infections of the nervous system, all forms of gastro enteritis and food poisoning, obscure pyrexia, and tuberculosis At Sheriff Hill, nearly half of the bed accommodation is reserved for tuberculosis of two special categories—bone and joint disease, and miliary lesions of the meninges and lungs Indeed, it was in a side ward of the pavilion devoted to the latter conditions that the patient with subacute bacterial endocarditis was treated Cases of pulmonary tuberculosis also have frequently been received in the cubicles of the hospital, and have been treated there until more appropriate accommodation was found This hospital is therefore already making a reasonable contribution to the solution of a national problem

The policy of using former isolation hospitals to provide accommodation for the tuberculous is being fully worked out in the Newcastle region In the Gateshead group, one of the two fever hospitals has been entirely given over to the treatment of pulmonary tuberculosis, leaving Sheriff Hill Hospital as the only fever hospital for an area with a population of nearly 200,000

Gateshead

JAMES GRANT
Medical Officer of Health

PUBLIC-HEALTH SALARIES

SIR,—In your article of Dec 30, you say of the new salary scales for doctors in the public health service "Unfortunately they do nothing to attract able men into the junior ranks, and little to give the service the prestige it needs" All doctors engaged in this service must surely endorse this statement If this scale is accepted, I hope that it will be with the appropriate degree of protest, and that steps will at once be taken to remedy this situation

Liverpool.

G STUART ROBERTSON

TROPIC OR TROPHIC ?

SIR,—May I call attention to my letter in your issue of Sept 30, 1944 ? In spite of Dr Burn's postulate, the logic is all in favour of tropic Atrophy does not necessarily mean degeneration by lack of nutrition , severance of a nerve causes atrophy of the corresponding muscle by inactivity while the nourishing blood supply remains intact Perhaps, in view of the derivation of the word, atrophy should not be used in this case, but it does not seem that a substitute word exists The fact that some words are in use which according to our present knowledge are misnomers but which have acquired general acceptance by tradition (e g , hysteria as derived from uterus) does not justify the creation of new misnomers with full consciousness of that fact It is to be deplored that many scientists do not attach more importance to the correct use of scientific language than the common man who, following the manner of the majority, uses I and me interchangeably, ignores the accusative of who, and does not even "feel badly" about it

Flushing N Y

ARTHUR E MEYER

THE LIQUORICE STORY

SIR,—In your annotation of Sept 23 on the interesting observations by Professor Borst and his colleagues, published in the same issue, you remarked "This fascinating investigation in Holland provides an interesting point of contact between those who work on plant hormones and the researchers in animal endocrinology" I would, therefore, like to draw your attention to the results obtained by Costello and Lynn[1] They noted that fluid extracts of glycyrrhiza contain œstrogenic principles (probably œstriol), an antihormone, benzoic acid, and two other non œstrogenic substances The deoxycortone type of reaction noted by the Dutch workers may presumably be due to œstriol, and may therefore explain the failure of the succus preparations used by them in Addison's disease and in rheumatoid arthritis

THE FALSE "ACUTE ABDOMEN"

SIR,—During twenty three years at sea I have operated on four cases of perforated peptic ulcer In the same period I have seen three cases in which the symptoms resembled those of an acute abdominal disorder but recovery took place without operation In cases of board like abdominal rigidity I follow an unorthodox routine The patient is given either morphine or 'Omnopon' in fairly large doses while the operating theatre is being prepared , on board ship this takes about three hours Though frowned on by surgeons, this is, I suggest, good practice in the conditions prevailing at sea The patient is going to remain under the care of the same doctor, so there is no question of masking symptoms for another surgeon , and I believe that injection of an analgesic clarifies the diagnosis, as it did in the three cases described below In fact, it saved these three patients from operation It seems probable that had they been seen in hospital ashore, they would have been taken straight to the operating theatre for laparotomy

CASE 1 —Many years ago, at about 8 30 one morning, I saw a carpenter s mate who had woken up with acute abdominal pain He had no previous history of abdominal symptoms On examination his abdomen was board like Being in those days single handed with no nursing staff, I took a rather gloomy view of the case , but, while the operating theatre was being prepared, he was given gr $^1/_3$ morphine He gradually recovered in about four hours, and completed the three months' voyage without recurrence

Subsequent inquiry elicited the fact that the fan in his cabin had been playing on his abdomen all night , and the final diagnosis was abdominal cramp due to this cause

CASE 2 —A male passenger had had abdominal pain nine months before , no radiological evidence of gastric ulcer had been found Earlier his appendix had been removed At 8 30 A M he began to have acute abdominal pain He ate no breakfast and treated himself with one dose of tinct chloroformi et morphinæ and later two brandies I was called to see him at 3 P M There was board like rigidity of the abdomen, more pronounced on the right side but extending into the left iliac fossa Temperature 98 2°F Pulse rate 60 per min Heart and chest normal Urine no abnormality found Perforated peptic ulcer, probably duodenal was diagnosed The patient was given gr $^2/_3$ omnopon, and the operating theatre was prepared

From then on, his condition gradually improved At 5 45 P M he was comfortable, but no intestinal sounds could be heard and there was still guarding over the gallbladder area By 8 P M he had fully recovered A diagnosis of acute cholecystitis was considered, but was discarded because the rigidity extended into the left iliac fossa and intestinal sounds were absent

CASE 3 —Four days after operating on a case of perforated duodenal ulcer, I saw a male member of the crew who reported sudden abdominal pain no diarrhœa at that time no previous attack Temperature 97 6°F Pulse rate 96 per min Vomited twice Abdomen rigid all over but not quite board like Chest and heart normal Urine trace of albumin and sugar Pupils ankle jerks, and optic discs normal

Recently perforated peptic ulcer was diagnosed and the operating theatre prepared Omnopon gr $^1/_3$ given Rigidity gradually decreased and diarrhœa ensued Final diagnosis —gastro enteritis

The possibility of tabetic gastric crisis was not investigated in the first of these cases but was excluded in the last two I have observed board like abdomens in both diabetic coma and uræmia, but these were excluded in these three cases Salt deficiency was not a causal factor in either of the last two cases, which occurred in comparatively cool weather

Goldstone and Le Marquand[1] reported cases of "acute abdomen" due to acute myositis (Bornholm disease) in which the patients were saved from operation only by the recognition of an epidemic In the cases described here, however, there was no question of an epidemic , and the onset, unlike that in all but one of the cases recorded by Goldstone and Le Marquand, was sudden

---

[1] Goldstone B W Le Marquand H S *Lancet* 1946 ii 267

Spontaneous healing of a peptic ulcer is possible, but it is difficult to believe that it occurred in each of these three cases Sometimes surgeons operate on what seem to be typical cases of perforated peptic ulcer and find no perforation, and in this connection Avid[2] mentions "formes frustes" These difficult cases usually seem to be in young patients My three cases were in young men, aged 25–35 years

On board ship cases are usually seen very early, which gives the ship's surgeon an advantage over his colleagues ashore With acute abdominal disorders the prognosis is probably very little affected by a delay in operating of up to twelve hours from the onset, and during this period, with the help of a powerful analgesic, the false "acute abdomen" will have declared itself, so that some delay in operation is justifiable

Ltd London

H M ROYDS JONES

PURIFICATION OF VACCINE LYMPH WITH PHENOL

SIR,—Gordon[3] in 1925 found that vaccinia virus is strongly resistant to phenol, since even a 1 in 20 solution does not completely destroy it, and Stevenson and Butler[4] used 0 5% phenol to prevent accidental contamination of vaccinia in the embryonated egg Gins[5] and Lehmann[6] advocated the purification of vaccine lymph with phenol, but it was not generally used in the routine preparation of lymph Last year McClean[7] reported that phenol in a final concentration of 0 4% has no adverse effect on the potency of vaccine lymph, and will so reduce the number of contaminating bacteria that the lymph can be issued for vaccination a fortnight from the date of trituration of the crude pulp, moreover, phenolised vaccine lymph kept at a temperature below 0°C maintains its potency with a good reserve margin even after a year from the time of its preparation

TABLE I —COMPARATIVE VIABLE COUNTS

Batch no	Colony count (thousands per ml)											
	Glycerinated lymph						Phenolised lymph					
	A	B	C	D	F	F	A	B	C	D	E	F
1	∞	∞	100	60	40	20	∞	12	11	10	8	4
2	∞	∞	80	60	30	20	∞	14	14	12	6	3
3	∞	∞	60	60	30	16	∞	14	12	10	8	4
4	∞	∞	80	50	30	14	∞	10	10	9	6	3
5	∞	∞	70	60	20	14	∞	8	8	6	5	4

∞ = too many to be counted accurately
A = immediately after preparation
B = a fortnight ,
C = 2 months ,
D = 6 ,,
E = 9 , ,,
F = 12 , ,

These findings of McClean have been confirmed in an investigation at the Stack Medical Research Laboratories at Khartoum Five batches of vaccine lymph were prepared The bellies of five sheep, the vaccinifers, were shaved and lightly scarified with a fine wire gauze, and seed lymph of high potency was rubbed in with the gloved left hand No dressing was applied to the vaccinifers, and no antiseptic was used for the crude pulp, which was scraped four days later The takes were good and the yields soft and adequate in quantity The pulp from each sheep was divided into two equal parts one part was glycerinated in the usual routine way—i e, 4 parts by weight of 50% glycerin solution containing 0 05% clove oil were added to it, triturated, and kept at temperature below 0°C—and the second half was treated with phenol according to McClean's method.[7] Thus five batches of glycerinated vaccine lymph and five phenolised batches were available for comparative bacteriological tests and potency titrations

TABLE II —COMPARATIVE POTENCY TITRATIONS

Batch no	Dilution	Glycerinated lymph					Phenolised lymph				
		A	B	C	D	E	A	B	C	D	E
1	10^{-4}–10^{-6}	+ +	+ +	+ +	+ +	+ +	+ +	+ +	+ +	+ +	+ +
	10^{-7}	+ +	+ +	+	+	+	+ +	+	+	+	+
	10^{-8}	+	+	+	+	+	+	+	+	+	+
2	10^{-4}–10^{-6}	+ +	+ +	+ +	+ +	+ +	+ +	+ +	+ +	+ +	+ +
	10^{-7}	+ +	+ +	+	+	+	+ +	+	+	+	+
	10^{-8}	+	+	+	10	10	+	+	+	+	8
3	10^{-4}–10^{-5}	+ +	+ +	+ +	+ +	+ +	+ +	+ +	+ +	+ +	+ +
	10^{-6}	+ +	+ +	+ +	+ +	+	+ +	+ +	+ +	+ +	+ +
	10^{-7}	+	+	+	10	8	+	+	+	+	10
	10^{-8}	+	+	10	6	4	+	+	4	6	4
4	10^{-4}–10^{-6}	+ +	+ +	+ +	+ +	+ +	+ +	+ +	+ +	+ +	+ +
	10^{-7}	+	+	+	+	+	+	+	+	+	+
	10^{-8}	+	+	10	6	6	+	10	6	8	8
5	10^{-4}–10^{-6}	+ +	+ +	+ +	+ +	+ +	+ +	+ +	+ +	+ +	+ +
	10^{-7}	+	10	4	6	3	+	+	10	4	3
	10^{-8}	10	4	2	4	4	8	6	3	4	2

A = immediately after preparation
B = 2 months ,,
C = 6 ,, ,,
D = 9 , ,,
E = 12 ,, , ,,

+ + = confluent take
+ = semiconfluent take.
Numerals indicate number of discrete vesicles.

Viable counts and potency tests were carried out simultaneously immediately after preparation, after a fortnight, after 2 months, after 6 months, after 9 months, and after 12 months from the time of preparation Viable counts were done by the usual pour plate method The vaccine lymph was diluted 1 in 1000 parts in distilled water and 1 ml was added to 15 ml of melted nutrient agar, shaken thoroughly, and poured in petri dishes incubated at 37°C for 24 hours, and the colonies were counted Three plates were used for each batch, and the mean of the colony counts was taken All precautions are taken to reduce the error inherent in the plate count method Tests for the presence of hæmolytic streptococci and gas producing anaerobes were made on blood agar plates, gentian violet blood agar plates, and Robertson's cooked meat media[8] The colony counts are shown in table I

For titrating potency, albino rabbits were used The hair from both flanks was removed with a depilatory powder[9] Then each flank was divided into areas of 14 sq cm each, which were lightly scarified with a needle and had 0 1 ml of the appropriate dilution rubbed in with a glass rod The rabbits were lightly anæsthetised with ether[10] To eliminate factors due to variations in sensitivity to vaccine lymph the same rabbit was used for both the glycerinated and the phenolised vaccines, one flank for each, and each batch was tested in two rabbits The results of vaccination were read on the 4th day and again on the 6th day of vaccination The results of takes are shown in table II

It will be seen that the contaminating organisms in the phenolised batches were reduced in a fortnight to within the limits allowed by the Therapeutic Substances Regulations, 1944, and that the phenolised lymph kept at a temperature below 0°C for a year showed no deterioration in potency and compared favourably with the glycerinated controls

Obituary

GEORGE LENTHAL CHEATLE

K C B, C V O, F R C S, Hon F A C S

George Lenthal Cheatle was born in 1865 He was educated at Merchant Taylors' School and King s College, London Hard work as a student brought him rapid qualification, and in 1887, while awaiting his house-appointments in King s College Hospital, he acted as assistant demonstrator of anatomy In 1889 he was appointed Sambrooke surgical registrar, in 1892 demonstrator of surgical pathology, and in 1893, on Lord Lister s retirement, assistant surgeon In 1900 he became full surgeon, teacher of surgical pathology, and honorary director of the pathological museum but shortly afterwards his work at King's was interrupted by his appointment as consulting surgeon to H M Forces in the South African War His service was recognised by mentions in despatches and appointment as C B

[Elliott & Fry

On his return to civilian life he carried out his routine work at King's and some smaller hospitals with vigour The accumulation of a large consulting practice was inevitable to a man of such distinction, but he remained a keen and conscientious teacher and a rabid research worker Apart from these, a growing interest in the Naval medical services was apparent when the German menace loomed on the horizon, a few years before the 1914–18 war, and he became a member of the Naval Advisory and Examining Board, and of the Admiralty Departmental Committee, Royal Naval Medical Service When war was declared he was given the rank of surgeon rear-admiral and made consulting surgeon to the Navy, serving as such throughout the war, mainly at Haslar but also at sea He was promoted K.C B in 1918

In both wars he declined the shelter of the base, deliberately accepting any risks wherever his ability could best serve the wounded In South Africa, on one occasion, he organised under fire a temporary operating-carriage in a train of wounded soldiers At Gallipoli he was in a hospital ship in waters where hospital ships could claim little immunity from enemy action

After the first world war he gave much time and thought to the reconstruction of the new King s College Hospital and its medical school General surgery, he considered, had reached such magnitude that some elements should be divorced, particularly urology and orthopædics, and the creation of these departments under distinguished specialists was largely due to his influence

In 1919 he was elected to the fellowship of King's College, and in 1923 he became senior surgeon of the hospital He also served on the committee of management and was chairman of the medical board In 1930 he retired from the active staff and was made consulting surgeon and emeritus lecturer in clinical surgery His activities, however, by no means ceased, his zeal for research was given greater scope and he at last found more time to contribute the results to the medical journals He was awarded in 1931 the Walker prize of the Royal College of Surgeons for his work on cancer, and in 1932 the honorary fellowship of the American College of Surgeons *Tumours of the Breast*, written in collaboration with Max Cutler, embodies the substance of his research into breast cancer

The year 1936 was the last landmark in this active life, when he undertook an extended lecture tour in the United States So that he might be eligible to lecture at Hines Hospital, Chicago, a privilege accorded to none but American nationals, he was granted American citizenship for one week, an almost unprecedented concession which he greatly appreciated

To this outline of his life we add the following tributes from his friends

J E writes ' As a teacher Cheatle was unorthodox for him the platform had little appeal, his intrinsic originality rebelled against the set lecture, the recital of the textbook, and he welcomed the distribution of systematic lectures to his colleagues His method of teaching was insidious and penetrating insidious since his listeners would leave with the impression that he asked their opinions because he valued them, and such corrections as he made were merely expressions of his view, penetrating, as I can affirm, for I remember to this day the lessons learnt at his tutorials more vividly than those from any other teacher He was at his best with a small class, either holding a clinical demonstration in outpatients or in his private laboratory filled to overflowing with his personal histological sections Some six of us closeted in his sanctum forgot the outside world, time meant nothing, carried away as we were by his enthusiasm in the demonstration of those beautiful sections and their significance Not only was morbid histology learnt, we were infected by his tireless energy to unravel pathological problems in those undergraduate days, the better to be equipped for their solution he inspired confidence and courage to succeed, and the urge that hard work alone could achieve success His chosen subjects were bacterial infections and the genesis of tumours, notably the latter, using as his material giant sections, cut with the giant microtome of his own design These sections had first to be studied with the naked eye, then with a low-power magnifying glass, ultimately working up to the highest magnification The object of giant sections was to show the normal, the transitional, and the established growth tissue in one piece His methods demonstrated the relation of Paget's disease of the nipple to underlying carcinoma, indicating the need for radical surgery Later researches showed that areas of leucodermia, sclerodermia, and Head s points of maximum intensity were likely infecting agents of superficial malignant disease

" Lenthal Cheatle not only taught us the way to work, he was a patron of the various activities so important in the life of a medical student He took a lively interest in the medical society renamed in his time the Listerian Society, of which he was president He encouraged outdoor games, particularly lawn-tennis, and presented a challenge cup for the annual singles championship, for many years he was president of the lawn tennis club As a student he was himself a keen cricketer and a prominent member of the inter hospital cup team, in later life fishing and golf were among his interests

" As a surgeon care, patience, and precision were his outstanding qualities, but he did not lack surgical boldness and brilliance in emergency His technique followed the orthodoxy of his time, but he readily accepted and explored any novelty Although an ardent disciple of Lister and Watson Cheyne, he was among the first at King s to become wedded to aseptic surgery, though not forsaking entirely the antiseptic, especially in skin preparation. No surgical innovations are associated with his name but he was responsible for valuable modifications of the set operations which his co workers were pleased to adopt No instrument, excluding the Spencer Wells hæmostat, is more widely used than Cheatle s forceps, it will be found in every hospital, nursing home and maternity institute throughout the civilised world The grace of its shape, the poise of its neck, its utility, in many respects portrays its inventor For he like his brother Arthur H. Cheatle, was richly endowed by Nature

' Tall, slender and upright, with a winning smile, and a keen eye that missed nothing Cheatle was welcomed by every society and social scale in any country he was the perfect ambassador, as his titles cavaliere uffiziale of the Grand Cross of Italy, associate of the Order of St John of Jerusalem, and chevalier of the Legion of Honour bear testimony Yet he was simple in his tastes, very human, and imbued with an overwhelming care for the welfare of his fellow creatures Kind and generous to his patients, he also offered material aid and encouragement to students and young graduates striving to climb the slippery ladder to their ambitions, and he was energetic in his efforts to help or defend the underling

His passing marks the end of an era He assisted Lister at his last operation. Watson Cheyne, Cheatle, and Arthur Edmunds were the connecting links between the old and the new, and the great advocates of the principles and practice of Listerism Each, through life, was impelled by the magnetic influence and the noble example of the great master to research for the benefit of mankind No greater tribute could be paid to Lenthal Cheatle than that he maintained the high tradition, he did his best "

C P G W, who served with Cheatle in the South African War and the first world war, recalls how back at King's after the war as his registrar

"I became interested in his thorough investigations of carcinoma of the breast with large sections Cheatle was an enthusiast and a surgical microscopist of the first order, and there can be few surgeons who during their lifetime have had such clinical experience of cancer of the breast, for he often performed ten or more radicals per week as a routine He had a charming personality, everyone who came in contact with him was 'my dear boy,' and he was beloved by his house surgeons and registrars, and his patients worshipped him Handsome, tall, and suave, with a delightful manner, he will long be remembered at King's "

J C B recalls that early in his surgical life Cheatle's mind "was turned to, and indeed we might say swamped by, pathology", for he gave the impression of caring for little else

"He used to run into the laboratory nearly every afternoon, perhaps with another specimen which he would orientate, give an instruction as to cutting more sections from a certain specimen, pick up such sections as were ready, and hurry off home to study the same, a proceeding which often lasted till the early morning With such preoccupation he had few interests outside, and indeed was to some extent casual in practice Scientific meetings did not interest him, but anyone mentioning a problem was promptly invited to come to the laboratory and work it out, this without it entering his mind that there might be no room or conveniences He was generous almost irresponsible, in money matters it was practically impossible to get him to attend to the annual statement of accounts of the laboratory, and there was competition among cabmen to pick him up in Harley Street, about 1 45 P M Particular, almost debonair, in his dress, he retained the top hat and tail coat long after they had been discarded by others He had a mannerism of sighing deeply before answering a question, a subconscious imitation of Lord Lister as I have been told People meeting him were made to feel at home at once by his friendliness, yet he was reserved about his private life, and it is comforting to know that he passed away peacefully at the home of his daughter "

A concluding tribute comes from H O E

"Cheatle had an arresting personality He loved the unorthodox, and practised it in all he did One might have regarded him merely as a poseur if it were not for the solid merit of his clinical and pathological work He did not use a private car, and it was always a matter for astonishment when a London taxi cab of the early '20s pattern disgorged on to the steps leading to the main hall of King's College Hospital the model of late Victorian sartorial perfection which Cheatle invariably was He used to call it 'maintaining the dignity of Harley Street' He carried this elegance even into designing the white coats he wore at outpatients and during his ward visits He smoked cigarettes continually, using a long holder with a mechanical device for ridding itself of the unexpended portion of the cigarette

"A precise operator, he was always anxious to make the operation appear, as he used to say, 'like a picture in a book' To be his house surgeon was an experience, for one never knew into what unusual action Cheatle's original mind would lead him He was capable of making a withering remark to a junior who was guilty of slipshod work or lazy thinking, but one never resented it, for it was always well meant Despite all these eccentricities, his zeal was unquestioned He had a real passion for research

"He was always happy when his ward round was over, so that he could rush away to the little room in the hospital where was housed the giant microtome of his invention There his technician would be cutting and staining sections of the whole breast removed at operation Those sections that were ready for examination would be wrapped up in a brown paper parcel for Cheatle to take home to Harley Street, where, in a little room on the first floor overlooking Devonshire Street, he used to keep them in a state of apparent disarray There seemed to be thousands of them littering this room, huge plates of glass, 10 inches square It was fascinating to spend an hour or two with him there, and none would enjoy it more than Cheatle himself He was not perhaps gifted with powers of lucid explanation, and was a little impatient if one was slow to see his point, but his opinions were based on the sure ground of morbid histology, and students and junior colleagues fortunate enough to be taught by him something of the pathology of the breast as he conceived it will not readily accept any alternative views His uncompromising attitude towards his critics may, perhaps, be the reason why his work does not seem to have received quite the recognition in this country which its worth undoubtedly deserved "

Sir Lenthal Cheatle died on Jan 2 His wife, formerly Miss Clara Jopp died in 1942, and there were three sons and a daughter of the marriage

ARTHUR JOHN HALL

Kt, M A, M.D Camb, Hon D Sc Sheff, F R C P

IN 1889 Arthur Hall returned to Sheffield from Rugby, Cambridge, and Barts to join his father in general practice He soon realised that another task lay ready to his hand, and with his appointment as assistant demonstrator in physiology at the Sheffield medical school he embarked on a life of unusually strenuous endeavour

At the turn of the century provincial medical schools were mostly very poor relations of the metropolitan centres of medical education, and it was of the utmost importance to grasp the opportunities offered by the establishment of new provincial universities When its new school was opened in 1888, Sheffield had a long leeway to make up buildings, equipment, and staff were all far behind the requirements of a self-contained medical school The prospect was enough to daunt the courage of the stoutest But Arthur Hall was peculiarly suited to bring about the radical changes required A clear insight into the difficulties of the situation, combined with steady optimism, a power of clear dramatic expression on platform and in committee, single-mindedness of purpose and subordination of private interest in the main object—these and other special qualities quickly collected round him a band of devoted workers Continuously but unobtrusively he guided the development of the school, and after establishing a department of physiology he turned his attention to organising a department of pathology

A colleague relates "He was always known as 'Lord Arthur,' but 'King Arthur' might have been more appropriate since the round table technique was a familiar device with him to promote professional harmony This promotion of harmony had for him a high priority With two large general hospitals, a municipal hospital, a separate maternity hospital of international repute, and a children's hospital, the chances of professional exclusiveness, jealousy, and friction were at a premium It is not too much to claim that everyone who was a member of those medical staffs *during the first thirty years of this century* would acknowledge that Hall's had been the major influence in building up the present background of good will He founded a Combined Staffs Club bearing the motto *Floreat Amicitia*, which now flourishes under the name of its founder Very early in the century he also founded an abstracts club which met at his own house and pooled the results of medical reading While surrounding himself with an aura of elaborate courtesy which rendered him rather unapproachable to many, his more genuine innate qualities were candour, openness to reason, and a personal kindness for which no trouble was too great No single person will ever know the extent of his kindnesses for they were all bestowed in secrecy "

Hall's devices to attract a first-rate staff to a school growing rapidly from small beginnings were ingenious:

Not seldom he would get himself elected to a newly formed chair and hold the post for a year or two till he could find a suitable occupant. This method, known to the profession outside Sheffield as musical chairs, was successful in obviating the appointment of an unsuitable candidate merely because he happened to be the only one available at the moment of first foundation. The negotiations through which Sir Edward Mellanby was appointed to a Sheffield chair were largely instigated by Hall. He also played a major part in the events which led to the granting of a charter to the University of Sheffield in 1905.

Clinical and administrative ability are not often closely associated, but Hall was a man who, if not of the very quickest intuition, yet by the solidity of his judgment and by his powers of minute observation, was able to advance medical knowledge. And he won his reputation as an administrator against a background of clinical achievement. His handling in 1918 of the new appearance of epidemic encephalitis was a masterpiece of accuracy and soberly progressive outlook and he chose this disease as the subject of his Lumleian lectures to the Royal College of Physicians in 1923.

After he retired from the chair of medicine in 1931 he continued for many years to serve as a member of the university council and of the board of the faculty of medicine. Progressive deafness, however, led to his retirement from active participation in university affairs. Nevertheless he continued to interest himself in the progress of events in the medical school and in medicine generally.

"There was always a warm welcome for friends who visited him," writes G. A. C. "and his never failing sense of humour was evident in the joking references he frequently made to his deafness. Yet this deafness must have been a sad blow to one who so thoroughly enjoyed participating as a 'cellist in quartets. The only complaint he expressed about his deafness was that it prevented him hearing the voices of his grandchildren. Naturally a man of retiring disposition who disliked publicity, he was happiest in the company of one or two intimate friends. Those who were admitted to this intimacy will always remember with affection the personality in which courtesy, wisdom, generosity of nature, humour, and high principles were all blended. He was indeed the green fingered gardener of the Sheffield school of medicine full of sympathy and understanding for the plants he cared for. His energy and enthusiasm were not guided by personal ambition but by a fine sense of loyalty to local institutions and to the profession of medicine."

His natural scientific bent had freer scope in the leisure his retirement brought, and his lively curiosity and keen observation were seen in his papers in our columns and elsewhere on such subjects as blinking, the parkinsonian smile, and cramp and salt balance. Though he gave unstintingly of his time and energy to Sheffield he had many outside interests. He had been elected F.R.C.P. in 1904 and he served the college as councillor, examiner, and censor. He examined for at least nine universities, and the quality of critical kindliness which led to this choice is made clear by A. I. G. McL.'s recollection of the membership examination:

"Hall pointed to a specimen jar containing a liver but at first I was at a loss to tell him what was wrong with it. He gently said 'Look at the bottom of the jar,' and there amongst the debris were things like grape skins. After that we had an animated discussion about the behaviour of hydatid cysts. When I went to Sheffield in 1934 he was already a legendary figure. He had retired from the chair of medicine in 1931, but he still retained his interest in clinical medicine, and his trim, dapper figure looking years younger than his actual age could often be seen at the Royal Hospital, where one of the wards was named after him. A man of great culture and urbanity, he was always approachable and ready to advise his younger colleagues. Of his kindness I can speak with feeling."

As was perhaps inevitable for one who had been associated all his life with Sheffield, he was an authority on pulmonary industrial diseases and he was for some years chairman of the Medical Research Council's committee on pulmonary dust diseases and a member of the Industrial Health Research Board. In 1930 he attended the international conference on silicosis in Johannesburg. He was also a member of the Radium Commission.

In 1928 Sheffield had conferred on him an honorary D.SC. In 1936 he was knighted and the same year his friends at Sheffield presented him with his portrait by Mr Ernest Moore (which we reproduce in part).

A. E. N. writes: "However powerful he was in dominating any situation for which he had direct responsibility, Hall never interfered with the freedom and responsibility of his colleagues or assistants. The one thing which thoroughly aroused his disapproval was lack of energy or interest in working for the good of the medical school. When the time came for his retirement he retired completely, and rigorously abstained from all interference. Thus his opinion was often spontaneously asked for. His medical teaching was sound and he conscientiously concentrated on bringing out the less gifted student. At special demonstrations he was clear and stimulating. Memory was rendered easy by punctuation with scraps of sardonic humour.

"His married life was remarkably happy, and the loss of his wife quite suddenly a few years before his own death made visible inroads into his reserve of health and enjoyment, but he endured all without complaint."

He died on Jan. 3, at the age of 84.

GATHORNE ROBERT GIRDLESTONE

M.A., D.M. Oxfd, F.R.C.S.

As we announced last week, Mr Girdlestone, of the Wingfield-Morris Orthopædic Hospital at Oxford, died on Dec. 30. Son of the Rev. R. B. Girdlestone, honorary canon of Christ Church, Oxford, he was born in 1881 and educated at Charterhouse, at New College, and at St. Thomas's Hospital which he entered as a university scholar in 1908. His first surgical post outside St. Thomas's was at the hospital near Oswestry now called the Robert Jones & Agnes Hunt Orthopædic Hospital, where for five years he worked both under the guidance of Sir Robert Jones and under the inspiring influence of Dame Agnes Hunt. At this time he had the misfortune to have a serious motor-cycle accident, which left him with a lung lesion. It was after this injury that he decided to dedicate his life to the care of crippled children. He had inherited his father's deeply religious nature and he entered orthopædic surgery with a sense of mission.

[Lafayette

At the beginning of the first world war Girdlestone served in the Royal Army Medical Corps, but his lung lesion prevented general service. In 1916 he was attached to the 3rd Southern General Hospital, Oxford, in charge of the orthopædic centre, an organisation which he had formed and which developed rapidly from the initial 56 beds to 400. With the help of Robert Jones, he took over some huts from the War Office which were re-erected in the grounds of what was then the Wingfield Convalescent Home, Headington, a small institution which had been founded in 1870. These huts were used by the hospital for seventeen years. In 1919 the Ministry of Pensions acquired the Wingfield Hospital as an orthopædic hospital for pensioners, though a 22-bed ward was reserved for the treatment of crippled children, but in 1922 the whole hospital was transferred from the Ministry of Pensions to the Wingfield Committee, and Girdlestone was made honorary surgeon and director. In 1930 he enlisted the sympathy of Lord Nuffield, with whose help the hospital was rebuilt and opened in 1933. His friendship with Lord Nuffield was also instrumental in gaining the latter's interest in the future of the Oxford medical school, which led to the Nuffield endowment of £2 million. In May, 1937, he was made Nuffield professor of orthopædic surgery, the first to hold a chair in orthopædic surgery in this country, but he resigned this post at the beginning of the late war He was then appointed regional orthopædic consultant to the E M S and honorary regional consultant to the Army and to the Ministry of Pensions In 1942 he was elected president of the British Orthopædic Association Outside his professional work he was a first-class golfer In his student days he represented Oxford, and only three months before his death he reached the semifinals in a competition at St Andrews

Girdlestone's entire medical life was given to building an organisation which would realise the ideal trilogy of Hugh Owen Thomas and Robert Jones for the treatment of crippling conditions ‘rest—surgical treatment—fresh air” To that end he launched a propaganda campaign with Robert Jones, initiated in 1919 by the publication of a plan for the organisation of orthopædics on a regional basis They referred to the pioneer work of Miss Hunt in Baschurch, the place where they had first met In 1920 both Robert Jones and Girdlestone organised the Central Council for the Care of Cripples of which for some time the latter was joint honorary secretary In 1925 he published in monograph form a scheme for the care of crippled children, basing his ideas on his experience at Headington, where the Oxford Orthopædic Region was given as an example for others to follow Already the orthopædic organisation at Oxford served, apart from the central hospital (the Wingfield-Morris), eleven outside clinics and four general hospitals In 1937, at Lord Nuffield's request, he visited South Africa to prepare a plan for the development of orthopædic surgery there This plan was subsequently fulfilled, and the National Council for the Care of Cripples in South Africa was another outcome of his visit He attracted to himself men from all countries who spent valued months and years working with and learning from him at Oxford He had a breadth of outlook that knew no geographical or national barriers

Conscious that functional recovery is the ultimate aim in traumatic surgery, he was a firm advocate of the segregation of accident cases from the care of the general surgeon to that of the orthopædic surgeon, and he was behind those who organised the accident service at the Radcliffe Infirmary, Oxford, in 1939, which, since its beginning, has been attended by the staff of the Wingfield In 1948 he suggested a plan to integrate the regional orthopædic and accident service within the frame of the new National Health Service When in that year he retired from his active duties, the posts he had created and held were occupied by younger men who had worked with him Finally, in 1949, he was one of those who asked the help of Lord Nuffield to integrate the whole of the orthopædic, traumatic, research, and teaching activities of the Oxford orthopædic region into a single structure, and Lord Nuffield offered £50,000 for the purpose When he died he was contributing to this organisation—the Nuffield Orthopædic Centre—as the culmination of his life-work

A Q W writes "Girdlestone could justifiably have said of the Wingfield what Louis XIV said of the State, but he would have been the last person in England to have done so His genuine humility would never allow him to claim more than a share in the evolution of all that the Wingfield is today Yet those who knew him and followed the growth of his cherished institution realise that in truth the Wingfield was G R G His vision and pertinacity created the physical Wingfield and overcame the difficulties which lie in the path of all pioneers That in itself was great work and called for a personality which is given to few men, but can never theless be paralleled in other branches of medicine But G R G created far more than the buildings and organisation of the hospital He inspired and maintained the spirit of the Wingfield, a spirit of clinical humility, of scientific honesty, of service, friendship, and happiness The most casual visitor must be struck by the happiness that extends all through the Wingfield medical, nursing, and lay staff, and patients

‘G R G's Wingfield was no moated castle whose inmates worked in self satisfied isolation Early in the history of its evolution, G R G realised the importance of going out into the surrounding neighbourhood to help with advice on orthopædic conditions A network of clinics in hospitals and elsewhere was set up where expert diagnosis and after care by the Wingfield staff was available for a large area round Oxford In effect this meant that a regional service in orthopædics centred on Oxford was in operation for much of the counties of Oxfordshire, Buckinghamshire, and Berkshire long in advance of the National Health Service Act When the appointed day came the Oxford Regional Hospital Board, therefore, was relieved of the detailed planning of a regional orthopædic service for this had already been in existence for some years The National Health Service Act might well have kindled a feeling of jealous resentment at so personal a structure as the Wingfield had become being handed over to an unknown and untried board, but G R G showed none of this and was from the very start anxious only to help in any way he was able He did not hesitate to accept the chairmanship of the board's orthopædic surgery advisory committee, where his services were of great value in extending the orthopædic service to cover the whole region."

Such ability as a planner and organiser was but the complement of Girdlestone's outstanding merits as a surgeon Both as a clinician and as an operator he was in the first rank His original technical contributions are many, among others his method of pseudarthrosis for advanced osteoarthritis of the hip, his tendon transplant for claw toes, his procedure of cap phalangectomy for hallux valgus, and his excision of the hip-joint in severe septic arthritis of the hip Among his many written works on clinical subjects his book on *Tuberculosis of Bone and Joint* is the most widely known, and he was engaged in finishing a new edition just before he died An article by him which we shall shortly be publishing reviews infection in the operating-theatre, in which he was profoundly interested His attitude towards post operative sepsis illustrated his honesty of mind A readiness to suspect his own technique first, and that of the theatre staff only secondly, gave him an approach worthy of the best scientific tradition Undeterred by difficulties caused by the rarity of cases of appreciable sepsis, he continued steadily to aim at the ideal of complete freedom from infections

Few people are privileged to see the dreams of their youth realised, but Girdlestone was one of them. He was convinced that one day the "homes for incurables" would be replaced by institutions created to prevent the crippling consequences of many diseases, and he made the dictum of Robert Jones, "spirit of happiness and orthopædic treatment" the maxim of his life A man of great affections, tender with sufferers, a sincere friend of his friends and all who surrounded him, he will live in the hearts of those who knew him and in the Wingfield which he brought to world repute from the first wooden hut he bought to be erected in 1919 He started where his teacher had left off, and he proceeded with untiring energy along the path clearly indicated by Robert Jones and Agnes Hunt From them he took the flaring torch, and it was still in his hands when he fell

J T writes "I have never known a man who had such capacity for love and being loved He has created in the Wingfield a sanctuary where he, the most modest of souls, was venerated like a new St Francis In his simplicity, directness, and affection for the poor and the crippled he had some features in common with the *poverello* of Assisi. His profound Christian beliefs, his inexhaustible energy to carry his work to a fulfilment, and his purity of appearance and bearing at all times and in all places made this parallel even closer But G R G was also a great planner and a good organiser

"As a true man of genius he never knew, or even suspected his worth He disliked public recognition and was happy sitting in the back row His modesty was apparent to the end by his refusing to have a memorial service dedicated to him It has been said of Hugh Owen Thomas that the myth woven about him during his life scarcely allows one to see the man himself I hope that the memory of G R G grows into a myth which becomes part of general medical teaching, that of a man who healed even more by the power of his love than by that of his supreme surgical skill Above all I am grateful to him for reaffirming my belief in the goodness of human nature"

In his early days at the Shropshire orthopædic hospital, Mr Girdlestone married Ina Chatterton, and she remained his companion and firm supporter till his death

CHARLES ERNEST WEST

B A, B M Oxfd, F R C S

Mr West, consulting aural surgeon to St Bartholomew's Hospital, died on New Year's Day at his home in South Devon, at the age of 77 Second son of the late C P West, of Ambleside, he received his earlier education at the Merchant Taylors' School, Crosby, where he obtained a classical scholarship admitting him to Balliol College, Oxford, in 1891 At Balliol he had a distinguished career and was in residence the unusual period of six years He was fortunate in his tutors, first Evelyn Abbott and then Sir John Conroy In his first three years he read classics, but after gaining a first in classics (mods) in 1893, he turned to chemistry and gained a first in natural science in 1895 He then joined the Oxford medical school and in 1897 won an open scholarship to St Bartholomew's Hospital In 1900 he was awarded the Brackenbury surgical scholarship and the Sir George Burrows prize, and took the B M degree Having served as house-surgeon to Mr Alfred Willett, he passed the final F R C S and was appointed a junior demonstrator of anatomy under Sir Holburt Waring At this time the hospital was improving and reorganising its special departments, and in 1902 West became first assistant to Mr A E Cumberbatch in the aural department When he succeeded Cumberbatch five years later he was an experienced and skilful operator and had already contributed a number of papers to the medical journals, besides undertaking bacteriological research with the guidance of Sir Frederick Andrewes and Lord Horder Between 1910 and 1920 he played an active part as a member of the otological section of the Royal Society of Medicine He was the new author of Diseases of the Ear in Walsham's *Surgery*, and joint author of *Operations of Aural Surgery* written principally for the aid of house-surgeons A joint paper on experience and results in operations on the labyrinth, which he read at the Royal Society of Medicine was the first important British report on this subject written from personal experience

After more than a decade in which he continued to carry on a large and increasing hospital and private practice, West startled his friends by deciding to retire, and he left London in 1921 He was elected consultant aural surgeon and a governor of St Bartholomew's Hospital, but went to live at Flushing, near Falmouth, where, after a strenuous life, he was able to enjoy one of his favourite hobbies, sailing and motor-boating Some years later he left Cornwall and moved to Sturminster in Dorset, where during the late war he joined the Home Guard, serving as major and medical officer of the 4th Dorset battalion In the first world war he had held a Territorial commission in the R A M C, and had been attached to the (Military) Hospital at Camberwell with other members of the St Bartholomew's staff, under Sir D'Arcy Power as commandant After the second war he left Dorset and took up residence at Budleigh Salterton in Devon.

With those who knew him well, West was a brilliant conversationalist but he was reserved and modest about his accomplishments and never sought society He was a keen critic of men and affairs and a connoisseur of good things, from wines to Persian carpets He was fond of writing and wrote well, at one time often contributing to the public press articles (usually anonymous) on non-professional subjects Though hardly a wit, he had a keen sense of humour—sometimes rather pungent He was a fearless speaker and a man of strong convictions, capable of rapid decisions With his gift of repartee he might have made a name for himself at the Bar, or with his talent for administration he might have become a captain of industry In the early days of motoring it was always a delight to accompany him to Olympia, for he was a man of many interests, and at the annual motor show he never failed quickly to recognise developments of practical importance His appreciation of music induced him to possess himself of a harp, on which he was no mean performer

West first married in 1908 After the death of his wife some years later, he married Miss Kathleen McCrossan, who was his devoted companion to the end He had no children

S S

THOMAS FRASER

C B E, D S O, M A, M.B, LL D Aberd, D L

By the death of Dr Thomas Fraser on Jan 2, Aberdeen has lost one of its most distinguished medical men and a well-beloved physician

He was born in 1872, the son of Provost Thomas Fraser of Kintore, Aberdeenshire From Robert Gordon's College he proceeded to Aberdeen University, graduating M A in 1894 and M B four years later While in general practice in the northern district of Aberdeen he was appointed assistant in the university department of materia medica and he was also clinical tutor at the Aberdeen Royal Infirmary

Early in his medical career Fraser took a keen interest in diabetes and he did research of distinction in this field Along with John Rennie, D SC, he made extracts of the islet tissue of the pancreas in *Lophius piscatorius*, the angler fish, of which, as Rennie and he remarked in their paper in the *Biochemical Journal* (1907), there was an ample supply at the Aberdeen fish market Fraser treated a series of diabetic patients with this extract, and in one patient he gave the extract by subcutaneous injection for four days, but he abandoned the method on account of the amount of the reaction caused by the hypodermic injection Accurate and easy methods were not yet available for estimation of the blood-sugar, though a tentative method, curiously enough, was published in the same volume of the *Biochemical Journal* by Edie and Spence It is probably true to assume that this attempt to use an insulin extract was the first on record, anticipating the work of Banting, Best, and Macleod in 1921

[MacMahon

The outbreak of war in 1914 found Fraser mobilised with the 1st Highland field ambulance, and he was in command of the 89th field ambulance at the landing at Helles in 1915 Later he saw action in Gallipoli, Egypt, and France, where he commanded the 51st Highland casualty-clearing station and later was A.D.M.S to the 47th London division For his services he was awarded the D S O, was five times mentioned in despatches, and was appointed C B E in 1920

At the end of the war he returned to his practice in Aberdeen, where his skill, wisdom, and unremitting effort earned the respect and affection of many patients, both in town and county, for as A. L writes "Fraser's dignified manner, his sound knowledge, and his wisdom were qualities which gave to his visits a peculiar charm and value, and although always busy he always had time to talk with either a patient or a colleague " He was appointed physician to the wards of the Aberdeen Royal Infirmary and lecturer in clinical medicine at Aberdeen University In his ward rounds he met the large number of post-war students, many of whom had themselves seen service, and to these he imparted both sound clinical teaching and the wisdom acquired in medical practice He had taken a full share in the discussion and negotiations before the introduction of National Health Insurance in 1911, and time had shown the wisdom of his advice Now in the '20s he again took a prominent part in the medical welfare of the north-east of Scotland

The joint hospital medical scheme had been a creation in the minds of the late Prof Matthew Hay and Sir Ashley Mackintosh, and Dr Fraser presided over the meetings of the Aberdeen Medico Chirurgical Society where the details of this important scheme were promulgated in 1927 His personal influence was of value in raising the large sum of £600,000 required to complete this great concept in 1936

Many honours came to him in the course of these years He was elected president of the Aberdeen Medico Chirurgical Society in 1927 He served on the council of the British Medical Association and he held the presidency from 1939 to 1942 He was a member of the General Medical Council from 1941 to 1946 His own university conferred on him the degree of LL D in 1939 and his city made him deputy lieutenant He is survived by his wife and two sons

HERBERT FRENCH

CVO, CBE, DM Oxfd, FRCP

Dr Herbert French, consulting physician to Guy's Hospital and formerly physician to H M Household, died in London on Jan 1, at the age of 75

He entered Guy's as a student in 1898, after taking a first-class in the final honours school of physiology at Oxford, where he had been a scholar of Christ Church As a student he won many prizes, and two years after qualifying in 1900 he was awarded the Radcliffe travelling fellowship In the same year he took the MRCP and was appointed medical registrar at Guy's His success in this post led to his election as assistant physician in 1906

[Weston's Studios

Up to the time of French's appointment Guy's had had few Oxford graduates on its staff, but in the next few years Hurst, Hunt, and Poulton were appointed, so that in 1914 all the four assistant physicians were Oxford men In 1907 French was elected FRCP and the following year he delivered the Goulstonian lectures on Medical Diseases of Pregnant Women On the retirement of Sir William Hale-White in 1917 French became physician to the hospital

In the first world war the foresight of Lord Haldane, at the War Office, had ensured that the services of many London physicians and surgeons should be available to the Army by giving them commissions in the Territorial Army on a part time basis, so that while continuing their civilian hospital work they could attend military hospitals in the London area. Soon after the outbreak of hostilities French was in khaki and he performed military duties throughout the war His programme was already full, for he had quickly built up a large consulting practice and his services were sought by general practitioners all over the country Nor did he neglect his duties at Guy's, where he was a popular and effective teacher

Up till about 1920 it was the custom for the assistant physicians at Guy's—and, indeed, at most other teaching hospitals—to do all the routine necropsies, and the experience gained by performing three or four post-mortems every week for many years laid the foundation of the remarkable clinical sense of the physicians of that epoch French, like his seniors and contemporaries, was not a specialist Nor would he have claimed to be a research-worker His interests embraced the whole field of medicine and by training and experience he was a sound all-round physician This outlook was appropriately reflected in his contributions to medical literature, which consisted mainly of articles in works of reference, such as Allbutt's *System of Medicine* and English's *System of Treatment*, in which his gift for lucid exposition found a worthy outlet His magnum opus, the still widely read *Index of Differential Diagnosis*, was a not unsuccessful attempt to approach clinical medicine through symptoms rather than by formal descriptions of diseases His small book, with Dr E E T Nuthall, on *Medical Laboratory Methods* was one of the earliest books for students on this subject

When he resigned from his hospital appointments in 1929 he was at the height of his fame But he was perhaps wise to retire at an age when he could still enjoy his leisure after so busy and exacting a professional career At his country home, Cudworth Manor, Newdigate, he indulged his taste for agriculture and he became a fruit-farmer, jam-maker, and cider-maker

One of his students recalls waiting on the steps of the colonnade at Guy's for French's handsome well-dressed figure, "for he was one of the few London consultants who did not change his sartorial habits in the 1914–18 war Up to his last round he always arrived in tail coat, top hat, white spats, and carrying a gold headed cane His teaching was always popular both for its intrinsic worth and also perhaps, for his habit of retiring in the middle of the round to the ward theatre so that teaching could continue while he and we indulged in a cigarette His hospitality will also be gratefully remembered In those days it was the practice of all members of the staff to give dinner parties for their firms every three months, and those at French's house were on a lavish scale, often ending with a flutter at roulette. He gave hilarious dances at Cudworth, where a guest might don wellingtons and help feed the pigs

P T writes "French *took great trouble* with his students and was especially keen on teaching them diagnosis—the methods of diagnosis and complications of disease One striking instance of his method was that he trained himself to imitate various convulsions, fits, and characteristic gaits *and to repeat these before his class of students* There must still be some of his former pupils who have seen Dr French having a realistic epileptic fit on the floor of the ward or demonstration room He was also equally keen on the routine work of having the clinical reports bound and indexed at the end of the year French commenced this work early in January many registrars were a year or more behindhand with this part of their work"

Dr French leaves a son and a daughter by his first marriage to Amy, daughter of Sir James Sawyer She died in 1946, and in 1948 he married Mrs Nora McDonald, who survives him

SIR PHILIP PANTON

W H McM writes "*Meeting Panton for discussion* was always a pleasure Seated beside him at his desk in the ministerial office which he shared with three others, one listened to a quiet persuasive voice advocating a change in the work or personnel of the laboratory A dissenting reply would cause his spectacles to slip down his *nose* and the corners of his mouth to fall in mild astonishment, a trace of firmness would then be discernible through the soft blueness of his eyes as they turned towards you When you eventually agreed and saw the wisdom of his argument—and you could be sure that any move he proposed would *be* to the *advantage* of all concerned—he would smile generously, opening his mouth in almost a gasp in a way which was highly characteristic At lunch at St Stephen's Restaurant after the interview he would inquire after many acquaintances, including the technicians and their families And then, pipe in *hand*, he returned across Parliament Square, waving farewell as he disappeared behind the sandbagged approach to Caxton House West His letters, often written hurriedly in an untidy hand, were notable for their conciseness and clarity, few of them ending without a sly touch of humour In committee he was sympathetic, unhurried, and watchful, having the knack of leading the meeting back to the point But he could be firm if opposed and the person who was not impressed with the advantages to the community of a service in clinical pathology might meet with a most withering and quite unexpected retort On the occasion of his pastoral visits red letter days in the laboratories, he found time to visit the pathologists in their homes, and he accepted invitations to speak in American hospitals

'At Otter's Pool he lived surrounded by the treasures he prized—books, portraits, and seascapes His bedroom opened on to a veranda which overlooked the lawn and his beloved watergarden, designed by him and largely fashioned with his own hands, for he was adept at building a wall, improvising a rustic bridge, or constructing a pool It was a garden such as would have delighted William Shenstone, while the waters were a paradise of ripples and shade for the fish he befriended But the regular visitor might notice changes in the landscape and colourful islands would appear in the waterways Beneath the veranda was the loggia adorned with stuffed birds, relics of his boyhood here on summer evenings he would reminisce on his early trips to New Zealand and the Faroes He was for his age unusually tolerant of cold and his habit of insisting on half open doors was sometimes hard to endure The grey flannel trousers, the shaggy Harris jacket and the pipe were old and trusted friends, as was his faithful Wu His illness showed itself not long after retirement and regretfully he laid his spade and wheelbarrow aside, but he continued to plan fresh improvements and enjoyed much of his time in the garden. For the rest he sat in his wicker armchair watching for the squirrel in the blue spruce tree and writing short stories which were fun to read At first he continued to attend meetings because of the opportunity they provided of seeing friends, but the journeys overtired him and he accepted defeat philosophically and with his usual good humour The mists of late autumn then settled on the pools and he saw the leaves of his favourite yellow catalpa fall for the last time on to the dewy grass "

SIR LEONARD PARSONS

R E S writes "The obituaries in the medical journals, and the moving address by Prof T L Hardy at the memorial service in Birmingham Cathedral, emphasised that Sir Leonard Parsons used his great gifts to great purpose As one living on the periphery of the Birmingham region, I would like to pay credit to another of his varied activities—his desire to make the National Health Service work for the good of all Perhaps this is typified by the entry opposite his name in the consultants' directory, that he was a specialist in general medicine and pædiatrics and that he was available anywhere in the region He willingly travelled any distance without thought of reward and often at great personal inconvenience If possible he preferred a consultation not to interfere with his going to church or the family lunch, especially when the grandchildren were present, but otherwise nothing stood in his way As he grew older so he seemed ever more willing to help others, especially mothers in distress If his example of coming to the periphery is followed by the younger generation and if credit for good work done there is appreciated centrally as it was by Sir Leonard Parsons, we can look forward to a fraternity living and striving together for a happier country "

Royal College of Surgeons in Ireland

The president and council of the college invite the submission of essays before Feb 1, 1952, for the Carmichael prizes (£150 and £100)

According to Mr Carmichael s will the essays should deal with the improvement of the medical profession with the view of rendering it more useful to the public and a more respectable body than it is at present The authors are also asked to consider the preliminary and moral education of medical and surgical students as well as the mode of conducting their professional studies Mr Carmichael also wished the authors to consider the most practical mode of rendering the qualifying examination as demonstrative as possible

Further particulars may be had from the registrar of the college, Dublin

Faculty of Radiologists

The faculty is holding a weekend postgraduate course at the Royal College of Surgeons, Lincoln's Inn Fields, London, W C 2 on Feb 17 and 18 Applications for enrolment should be sent to the secretary of the faculty, 45 Lincoln s Inn Fields, W C 2

Harveian Society of London

The Buckston Browne prize for 1950 has been awarded to Dr C J Gavey, F.R C.P, for his essay on the Management of the Hopeless Case

King Edward's Hospital Fund for London

The Fund has received a further instalment of £100 000 from the Nuffield Trust for the Special Areas Lord Nuffield provided that loans repaid to this trust should pass to King Edward s Hospital Fund In all £1,350,000 has now been received

The King has sent his annual subscription of £1000 for 1951 to the Fund

Prison Medical Services

Dr H K Snell, principal medical officer of Wormwood Scrubs Prison, has been appointed to be director of Prison Medical Services in succession to Dr H T P Young, who retired on Dec 31

Dr Snell qualified from King's College Hospital in 1921 and after holding house appointments there took his M B Lond in 1924 and his M D three years later He has served as medical officer at Wandsworth and Parkhurst prisons and at Broadmoor asylum His published work includes papers on the influence of war on drunkenness and attempted suicide

Society of Chemical Industry

The 70th annual general meeting of this society will be held in London from July 9 to 13, at the Imperial College of Science and Technology, South Kensington

Empire Rheumatism Council

Lord Horder, will take the chair at the annual general meeting of the council to be held at 41, Portland Place, London, W 1, on Wednesday, Jan 24, at 6 p m

St John Ambulance Brigade

Mr Frank Edwards, F R C S E, of Shrewsbury, has been appointed surgeon in chief of the brigade in succession to Dr Corbet Fletcher, of Hampstead, who has resigned Dr Marcus Scott, of Newington Causeway, London, succeeds Mr Edwards as deputy surgeon in chief

Institute of Hospital Administrators

The address of this institute and of its journal the *Hospital* is 75, Portland Place London, W 1

Irish Gerontological Society

This society was founded on Dec 6 The following officers were elected president, Prof W J E Jessop, secretary, Dr John Fleetwood, treasurer, Dr Paul Holland The secretary may be addressed at the department of physiology, Royal College of Surgeons, Dublin

Community Mental Health

Dr Russell Brain, F R C P, will open the conference on Community Mental Health in Practice which the National Association for Mental Health is holding at St Pancras Town Hall, London, W C 1, from March 12 to 13 Other speakers will include Dr T A. Ratcliffe, Dr Fanny Wride, Dr Mary Capes, Dr T M Ling, Dr Roger Tredgold, Dr Felix Post, and Dr J W Affleck Further information may be had from the conference secretary, 39, Queen Anne Street, W 1

Volunteers for a Cold

The Common Cold Research Unit at Harvard Hospital, Salisbury, needs more volunteers urgently because the island experiment, described in our columns last week, has given new ideas for studying the transfer of natural colds The unit is also trying to find out why school-children play such an important rôle in the spread of the common cold

Since the experiments at Salisbury started in 1946 over 2000 volunteers have visited the unit, some of them have paid as many as four visits But more volunteers, aged 18–40, are still needed They are offered 10 days' holiday with free travel warrant and pocket-money Applications should be sent to the medical officer, Harvard Hospital, Salisbury

Births, Marriages, and Deaths

BIRTHS

Browne —On Dec 25 at Newcastle upon Tyne, the wife of Prof R C Browne—a daughter

UNIVERSITY COLLEGE HOSPITAL

SINCE the introduction of the National Health Service, wo years ago, one of the more formidable problems has een the care of the aged sick General practitioners hroughout the country know well the difficulties of etting their aged patients into hospital Harold tassen, in an article called "Granny is Gone," has ingled out for criticism this aspect of the health service n Britain, and tells the story of one old lady who died f pneumonia, because she could not be found a bed in hospital (see Oglvie 1950) We hope to show in this article how a service, based on a hospital, can be evolved o provide better facilities for the care of the aged sick

Short Stay In Hospital

We have already described the state of affairs in St Pancras Hospital when this work was begun (Exton-Smith and Crockett 1949) It is now possible to give igures of the results of a year's treatment, and in so doing the patients have been divided into two categories In the first category are the "inherited" patients (those present at the time of the take over), in the second category the "new" patients (those admitted during the year June 1, 1949, to May 31, 1950)

The disposal, over a year, of 155 inherited patients is shown in table I These bare figures give rather a gloomy view of the chances of rehabilitation and ultimate discharge of patients who have been in hospital for more than two years We can say, however, that though 95% of these patients were at one time bedridden, by the end of the year their physical state and mental outlook had improved so much that the bedridden cases had been reduced to 10% The patients composing this 10% have gross physical deformities which make it impossible for them to sit in chairs Many of these deformities we believe were preventable

Table II shows the disposal, over a year, of 89 new patients Of the 29 remaining in the hospital, we consider that 18 (20% of the 89) are suitable for hostel accommodation , and in fact some of these patients are now awaiting the opening of a hostel which is to be attached to the hospital Only 11 of the 29 (about 13% of the 89) are regarded as irremediable Only a small number of new patients were admitted during the year, because the total number of beds allocated to aged patients is being reduced from 155 to 120

The considerable difference in the average length of stay of the two groups of patients has led us to consider whether these groups were comparable In one way they were not, for none of the inherited patients had been admitted direct from home they had come from other hospitals where they had usually already spent several months, and they were transferred to St Pancras Hospital because at that time there was no solution to their problem other than continued hospital care

We contend that in many of these cases this solution was not the only one and that if this type of patient be dealt with in the manner we outline below many needless hospital admissions will be avoided If so, a great saving will be made in hospital beds, the maintenance of which costs the community so much money and staff Indeed, if the existing beds were kept free of those who do not require hospital care, the 6000 hospital beds for the chronic sick* now unused through lack of nursing staff might turn out to be redundant We believe that the demand for still more nursing recruits, at a time when there are more nurses in the country than there ever has been in the past, is unjustified

Table I shows that 155 patients have been in hospital for an average of thirty-two months (at a cost of about £220,000) We believe that only in very exceptional cases need a patient remain in hospital for as long as thirty two months Table II shows that the average length of stay of the "new" patients is about ten weeks This suggests that if, in a period of 32 months, these 155 hospital beds had been employed for their proper purpose—the active treatment of the sick—they could have accommodated 1200 "new" patients at the same cost to the hospital This turnover in itself would have eliminated a long waiting list The longer the aged patient must wait before gaining admission to hospital the more difficult and longer his treatment becomes Waiting lists are thus conducive to long stay in hospital, the two tending to produce a vicious circle as the turnover diminishes

---

Society of Chemical Industry

The 70th annual general meeting of this society will be held in London from July 9 to 13, at the Imperial College of Science and Technology, South Kensington

Empire Rheumatism Council

Lord Horder, will take the chair at the annual general meeting of the council to be held at 41, Portland Place, London, W 1, on Wednesday, Jan 24, at 6 p m

St John Ambulance Brigade

Mr Frank Edwards, F.R C S E, of Shrewsbury, has been appointed surgeon in chief of the brigade in succession to Dr Corbet Fletcher, of Hampstead, who has resigned Dr Marcus Scott, of Newington Causeway, London, succeeds Mr Edwards as deputy surgeon in chief

Institute of Hospital Administrators

The address of this institute and of its journal the *Hospital* is 75, Portland Place, London, W 1

Irish Gerontological Society

This society was founded on Dec 6 The following officers were elected president, Prof W J E Jessop, secretary, Dr John Fleetwood, treasurer, Dr Paul Holland The secretary may be addressed at the department of physiology, Royal College of Surgeons, Dublin

Community Mental Health

Dr Russell Brain, P R C.P, will open the conference on Community Mental Health in Practice which the National Association for Mental Health is holding at St Pancras Town Hall, London, W C 1, from March 12 to 13 Other speakers will include Dr T A Ratcliffe, Dr Fanny Wride, Dr Mary Capes, Dr T M Ling, Dr Roger Tredgold, Dr Felix Post, and Dr J W Affleck Further information may be had from the conference secretary, 39, Queen Anne Street, W 1

Volunteers for a Cold

The Common Cold Research Unit at Harvard Hospital, Salisbury, needs more volunteers urgently because the island experiment, described in our columns last week, has given new ideas for studying the transfer of natural colds The unit is also trying to find out why school children play such an important rôle in the spread of the common cold

Since the experiments at Salisbury started in 1946 over 2000 volunteers have visited the unit, some of them have paid as many as four visits But more volunteers, aged 18–40, are still needed They are offered 10 days' holiday with free travel warrant and pocket-money Applications should be sent to the medical officer, Harvard Hospital, Salisbury

Births, Marriages, and Deaths

BIRTHS

bowel action can be produced at a convenient and predictable time

Medicolegal Reasons

We have found that many patients have been kept n bed after a fall, irrespective of whether or not they have sustained any real injury Some hospitals have been prompted to withhold attempts at rehabilitation of patients who have a tendency to fall for fear of adverse criticism in the coroner's court A tendency to falling s almost universal in aged patients, but can hardly justify such a nihilistic attitude as that In our unit 102 patients who were formerly bedridden now spend the greater part of the day sitting in chairs, or take part in walking exercises in the ward and gymnasium Except one patient who slipped on the floor (which was formerly kept highly polished) none has sustained any serious injury

Reasons of Expediency

It is always easier to keep aged patients in bed than to get them up, but the enthusiasm of the ward sisters in encouraging patients to activity does much to counteract such laissez faire Some believe, mostly out of sentiment, that people should be put to bed merely because they are old and " deserve a rest "

We have recently seen a lady of 91 who, after bronchopneumonia three years ago, had been kept in bed by well meaning and consequently overburdened relatives After two days in hospital she was sitting in a chair, and within six days she was walking She was in hospital only twenty-nine days and was able to return home fully ambulant

On the other hand, directly they are admitted to hospital, some patients who were ambulant at home lose their ability to get about For those living alone the stimulus to remain active is that of self preservation There are many without friends and relatives, and to survive they must at least be able to get to their front door to admit food and succour Once in hospital, such patients are often waited on hand and foot , the stimulus to activity is lost , they find no familiar pieces of furniture on which to drag themselves around , and they quickly cease to be mobile Here is a true iatrogenic loss of locomotion

Blind patients need not be kept in bed If they are led round the ward each day they soon come to know it as well as the familiar surroundings of their own home

DISCHARGE FROM HOSPITAL

Though it is a relatively simple matter to aid the recovery of the aged sick admitted to hospital, their ultimate discharge often presents a formidable problem Naturally the rate of turnover directly depends on the ease with which the patients can be discharged. Those who have been treated successfully in hospital can either be returned home or be sent to hostel accommodation

Return home—The difficulty of discharging a patient to his home is due not only (as some would have it) to the unwillingness of relatives to look after their aged parents but also to less obvious causes As a person gets older he adapts his life to his failing faculties, and his daily habits in the home are modified to fit in with what he can manage without assistance The sudden onset of an incapacity, be it major or minor, will upset the delicate balance between what the person can do and what he needs to do to continue his normal existence at home This precarious balance, which has been steadily built up over the course of years, can rarely be restored once the patient has been admitted to hospital, even though the precipitating incapacity which led to admission has been removed Where the balance before admission is not so critical, it is possible to discharge the patient to his home Nevertheless, such patients will usually need a home help, meals on wheels service, and outpatient supervision to enable them to carry on their home life successfully

Hostel accommodation—Where the balance between ability and necessity has become more precarious even the provision of these services will not allow the person to return home , and some form of hostel accommodation is essential Hostels for the aged are sadly lacking in most areas At the moment some 45% of the patients in this hospital have enough functional capacity to live fuller lives in a hostel than they are enjoying at present in hospital , but they remain because we lack other accommodation

Long stay annexes—A few patients still have considerable disability even after months of intensive treatment They need continued physical assistance and some general nursing care for their well being This type of patient is best cared for in the so called long stay annexe In collaboration with the Emergency Bed Service we have been able to transfer such patients to nursing homes under the control of the regional hospital board , and at the same time patients on the Emergency Bed Service waiting list have been admitted to the vacant hospital beds

Domiciliary Visits

We have already mentioned the part played by a domiciliary visit in promoting a quick turnover of patients But there are also other aspects of these visits to be considered

PURPOSE AND VALUE OF HOME VISITS

1 It is necessary *to establish a base line*, or a common standard, by which to judge the urgency of the need for admission to hospital The necessity arises from the present shortage of beds for the aged sick for we have to ensure that the available beds are used to the best advantage If such a common standard is to be maintained a physician from the hospital must visit the patients in their own homes , otherwise the hospital has to rely on reports from general practitioners, who may have different standards and use different criteria in judging the urgency of admission

Though adverse social conditions rather than physical disabilities sometimes make admission necessary, we find this exceptional The initial visit must therefore be made by a doctor who assesses the physical need, rather than by an almoner who will assess the social need (cf Macdonald 1950)

2 *To evaluate waiting lists*—We have received from time to time a list of patients on the " chronic " waiting list of the Emergency Bed Service for the St Pancras area When we visited such patients we often found that the physical condition had changed since their names were put on the waiting list , and in many cases the E B S had not been informed of such changes Thus some patients had died, others had already been admitted to a hospital, and many had recovered The particular value of a domiciliary visit may be illustrated by the following case

We were asked to see a woman aged 90, who was said to require urgent admission because of gangrene of the leg She was living in reasonable comfort in a first-floor flat and was cared for by an elderly friend On examination she was very weak, but not in pain There was auricular fibrillation and the left leg was blue and cold up to the groin, with no femoral pulse She did not want to come into hospital and the friend, who realised that she was dying, was most anxious that she should spend her last hours at home It seemed the kindest thing for them both to leave them be, for the friend was managing adequately and the patient was receiving attention from the district nurse We consulted with the patient's doctor who agreed to this course

3 *To assess the patient in his environment*—It is becoming clearer and clearer that by observing and treating a patient in a hospital, isolated from his normal environment, we may be going only half way towards promoting recovery in its broadest sense The hospital

Economic considerations aside, it is clearly right and proper that patients should spend as short a time as possible in hospital. The results to patients of long stay and neglect in Public Assistance institutions and hospitals are well known, and are responsible for the evil reputations of such institutions. As this geriatric unit, like most others, has grown up in what was once a municipal infirmary, it is satisfying to find that already the quick turnover has changed the attitude of prospective patients in the district. They are no longer hesitant about agreeing to admission, they no longer feel that their entry here will be the beginning of their "way to dusty death."

Attainment of a Quick Turnover

The way in which such a quick turnover can be achieved may be considered in three sections: domiciliary and outpatient treatment, ward treatment, and discharge from hospital.

DOMICILIARY AND OUTPATIENT TREATMENT

Every patient who requires early treatment to ensure his quick recovery must be admitted without delay. In order to select these cases, whenever a practitioner requests admission for a patient we see that patient in his own home or in the outpatient department. Most of them do not attend outpatients in the first instance; as a rule they have already taken to their beds, and so are seen in their homes. For every new patient attending the outpatient department, 4 are seen for the first time at home.

Great psychological benefit results to the patient from a visit by hospital doctors; he becomes at once an individual (rather than a mere name on a waiting list), known personally to the doctors who will be looking after him in hospital. Many patients receive outpatient treatment in the physiotherapy and occupational therapy departments, and these are brought to hospital by car or ambulance.

Large-scale domiciliary treatment, as practised by Dr. Bluestone (1949) at the Montefiore Hospital, New York, would reduce still further the numbers requiring hospital admission, and lessen the period of stay for those already in hospital.

WARD TREATMENT

Various detailed articles on the adaptation of modern therapeutic measures to the care of the elderly sick have appeared (Howell 1950, Cosin 1949, Warren 1948a, Crockett and Exton Smith 1950). The geriatric ward differs from the acute general ward in one important way. In the general ward, it is traditional for a patient to be in bed. Whatever the reason for his entry to hospital—be it merely the balancing of his diabetes, or the investigation of renal function—he is put to bed and kept there, for the convenience of doctors and to maintain, for the sake of the nursing staff, the orderly appearance of the ward. The diabetic accurately balanced for his immobile hospital existence will require, on returning to an active life, a radical change in his insulin dosage; but he will suffer no permanent harm. For the aged patient, on the other hand, such immobilisation is often disastrous, ending in permanent bedfastness.

Many of the reasons given for keeping patients in bed are not valid for the elderly. These reasons can be conveniently classified as medical, hygienic, and medico-legal, and reasons to do with expediency.

Medical Reasons for Rest in Bed

Heart disease.—Rest in bed in a young patient considerably reduces the amount of work the heart has to do. On the other hand, in the aged patient, whose normal activity is already considerably reduced by other than cardiac factors, long-continued bed rest produces little further reduction in the work of th heart. Bain (1950) states that three weeks in bed afte coronary thrombosis is quite long enough for an aged patient. Gavey (1949) agrees that three weeks is th optimum period of rest after coronary thrombosis, and in some cases a commode may be used after one week.

Patients with congestive cardiac failure or angi need not necessarily be kept in bed, but should allowed as much activity as their dyspnœa or pa permits.

Hypertension.—Some degree of hypertension, especial systolic, is a usual concomitant of old age, and no patie need be restricted in his activity or confined to b because of high sphygmomanometric readings alone.

Hemiplegia.—As soon as the period of shock followi a cerebrovascular accident is over, the patient mu become as active as possible. Generally a week aft the onset of a hemiplegia, he may sit in a chair a start his exercises (Warren 1948b). Patients wi hemiplegia are often left in bed for many months befo their treatment is considered; by this time the lim are contracted, stiff, and painful to a degree for whi the paralysis alone cannot be blamed. Even wh walking is never achieved the patient should re-educated sufficiently to lead a "chair-borne" existen and not put back to bed as "hopeless."

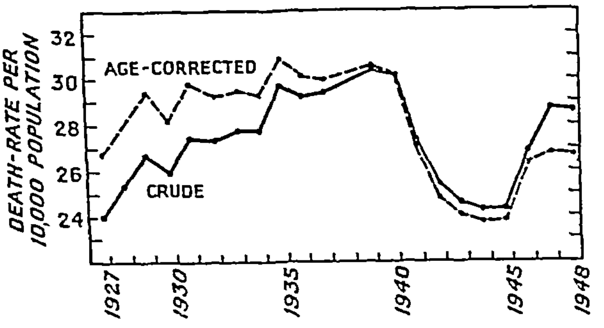
Arthritis.—Even as little as 15° of limitation of exte sion of the knees, in the presence of restricted ank movement, will prevent a patient walking; and su minor degrees of deformity easily develop insidious beneath the bedclothes. A long period in bed or encourages stiff painful joint deformities. The resti of a joint with chronic arthritis may temporarily relie pain, but any later attempt to recover function w bring with it more pain than ever before; so rest or alleviates pain at the expense of function.

Varicose ulcers.—Although varicose ulcers may treated effectively by measures involving rest in b this is by no means essential. In fact, most patien with varicose ulcers need not be admitted to hospi at all. Treated at home by the Dickson Wright 'Elast plast' method, they should remain ambulant (Riv 1951), and this is very desirable, for they are al to retain their independence, and do not become a burd to their relatives.

Neurological and orthopædic conditions.—Many su conditions may ultimately prevent patients walking e.g., late motor neurone disease, disseminated sclero tabes dorsalis, and ununited fractures of the lower lin For patients with such disorders rehabilitation will n be complete, but they should be encouraged to achie as much functional activity as possible. They c usually be taught to get about in wheel chairs, and th live as full a life as possible within the limits of t disability. Moreover, deterioration may be slow down, particularly in tabes.

Hygienic Reasons

It is an almost universal custom to keep an incontine patient in bed. Conversely, one often finds that elde patients confined to bed for long periods beco incontinent. Very often the simple measure of gett such patients up suffices to remedy their incontinen For those who remain incontinent when sitting out bed there are two devices which prevent continu soaking of their clothes. For men, the use of cond drainage is invaluable. A condom, from which rubb tubing leads to a bottle, is fitted over the penis, and this way an intra-urethral catheter, and hence t danger of a urinary infection, are avoided. Wom incontinent of urine (and of fæces) can be sat on a commo chair throughout the day, an inflated rubber ring bei interposed to prevent pressure sores. Fæcal incontine often responds to regular enemata, by means of whi



g 1—Mortality from circulatory diseases in Norway in 1927–48
Standard population = population of Norway in 1940

om these diseases in Norway in the period 1927–48 927 was chosen as the first year to be studied because was then that Norway adopted the inter Scandinavian omenclature of causes of death However, in 1941 he Statistical Central Bureau, which handles the gures for causes of death, adopted the international omenclature It has therefore been necessary to egroup the diagnoses of causes of death for the years 941–48 so that they tally as closely as possible with he diagnoses according to the inter Scandinavian omenclature, this regrouping was made in accordance ith directions given by the Statistical Central Bureau able I shows the synonymous diagnoses of the two omenclatures

MORTALITY FIGURES

Fig 1 shows that until 1940 there was a steady rise n mortality from circulatory diseases This rise was maller with correction for age than without such orrection—a feature which reflects the influence of the changing age distribution of the community From 1941 onwards there was a sharp fall in mortality, which was lowest in 1943–45 When the war ended mortality rose sharply The rise before the war, the decline during the war, and the subsequent rise are equally pronounced for each sex Expressing the mortality in 1938–40 as 100 (with correction for age), the comparable figure for 1943–45 was 78 7 for men and 78 6 for women, and for 1946–48 it was 87 3 for men and 88 1 for women

This decline began in the year that the inter-Scandinavian nomenclature was replaced by the international nomenclature We have concluded, however, that the change over can account for no more than a small part of the war time decline, and the subsequent rapid rise to the pre war level strongly suggests that the decline was real

TABLE I—CAUSES OF DEATH ACCORDING TO THE INTERNATIONAL AND THE INTER SCANDINAVIAN NOMENCLATURES

International	Inter Scandinavian
Pericarditis Endocarditis acuta et subacuta Endocarditis chronica (vitium organicum cordis) Alii morbi cordis	Pericarditis Endocarditis acuta Endocarditis chronica (vitium cordis)
Myocarditis acuta et chronica degeneratio myocardii infarctum cordis	Myocarditis chronica
Arteriosclerosis universalis Arteriosclerosis cordis embolia thrombosis aneurysma arteriæ coronariæ angina pectoris	Arteriosclerosis
Embolia et thrombosis cerebri Congestio pulmonum œdema embolia infarctum thrombosis pulmonum	Embolia
Aneurysma (sine aorta)	Aneurysma (sine aorta)
Gangræna	Gangræna senilis
Morbi venarum	Morbi venarum
Alii morbi organ circulat	Alii morbi organ circulat
Hæmorrhagia cerebri apoplexia	Apoplexia
Nephritis chronica	Nephritis chronica

Throughout the period from 1927 to 1948 the mortality from these diseases was highest in the oldest age groups Before the war the increase in mortality was confined to those over 60 years of age, and was greatest among those aged 80 years or more The decline during the war affected all age groups, but was greatest in the youngest groups Expressing mortality in 1938–40 as 100, then in 1943–45 it was 69 among those aged 20–39 years, 71 in those aged 40–59 years, 75 in those aged 60–79 years, and 89 in those aged 80 years or more (table II) The post war rise involved all ages over 40

In estimating the number of deaths from each separate cause between 1927 and 1948, we are hampered by the big changes during this time both in diagnostic criteria and in the system of statistical registration, and thus we must be most cautious in drawing conclusions Throughout the period, however, there were four main causes of death according to the inter Scandinavian nomenclature apoplexy, arteriosclerosis, chronic myocarditis, and chronic endocarditis (valvular disease of the heart) Chronic nephritis was a rather less important cause, and the other causes, both individually and collectively, played a minor part

TABLE II—MORTALITY IN 1943–45(a) AND 1946–48(b) RELATED TO MORTALITY IN 1938–40 WHICH IS EXPRESSED AS 100

Causes of death	Age-groups (years)									
	20–39		40–59		60–79		80 and over		All ages	
	a	b	a	b	a	b	a	b	a	b
Apoplexy			67	73	80	89	96	102	85	95
Arteriosclerosis			57	71	52	57	61	65	60	65
Chronic myocarditis			86	100	83	104	104	112	92	112
Chronic endocarditis	75	75	92	105	98	126	151	191	112	143
Chronic nephritis	50	50	47	43	51	46	50	41	50	46
All causes	69	58	71	77	75	88	89	97	81	93

During the whole period, apoplexy was the most important cause The mortality from this cause rose somewhat before the war, but only among those aged 80 years or more During the war there was a distinct, but not very well marked, decline for all age groups, and this was most evident in the youngest groups (see table II) Since the war there has been a definite rise in all age groups

Arteriosclerosis was for a long time the next most common cause, but from the middle 30s deaths from this cause declined considerably (fig 2) The decline was certainly not due to this disease having become more rare, it is attributable rather to the change in nomenclature, the main effect of which was an increase in notifications of death from chronic myocarditis, under which heading cardiac infarction is now registered (see table I) The decline in mortality from arteriosclerosis was accentuated during the war, but since then deaths from this cause have definitely increased

The greatest rise was in deaths from chronic myocarditis, the rise being most prominent in the oldest age group (fig 3) However, deaths from this cause also declined during the war, and after the war again rose

It is more difficult to judge mortality from chronic endocarditis because since 1941 this cause has been included with "other diseases of the heart" The figures from 1941 onwards are therefore misleadingly high (table II)

The most striking features of the chronic-nephritis figures (table II) are the conspicuous decline during the war and the comparatively moderate rise after the war doctor visiting the patient's home before admitting him to hospital will at once gain valuable information on which the whole treatment, course, and prognosis may be planned It is possible to see how the patient was managing to cope with his everyday life before his illness, or, in some cases, despite his illness Further, the relatives and others helping the patient will nearly always be at hand, and all the circumstances of the case can be discussed with them The relatives must never be given the impression that " granny is going away for good ", the idea should be inculcated that the stay in hospital is only likely to be temporary, so that granny's room is not given up the moment she goes out of it Also the strain the illness is throwing on those helping can be judged This is an important point in assessing the necessity for admission Incontinence, bed sores, and restless confusion at night are all conditions imposing on the relatives a nursing burden that very few can support

Finally, it is useful from the standpoint of prognosis to know the details of the patient's home—the number of stairs, the situation of water and lavatory, the proximity of shops, and the willingness of relatives to help On these facts one may often predict whether the patient will be able to return home once hospital treatment is finished

4 *To make contact with general practitioners* —Whereas formerly the plight of many old people was brought to our notice by such bodies as the Family Welfare Association, we now find that general practitioners seek our help in the first instance The general practitioner is, we hope, reassured to feel that he is not having to deal unaided with his aged sick, who are often among his most exacting patients By discussion with him the patient's management can be unified, and the usual dichotomy between home care and hospital care avoided Moreover, the bond between the general practitioner and his local hospital, which is rapidly weakening elsewhere, is in this particular service strengthened

RESULTS OF HOME VISITS

The following figures show the care arranged as a result of 127 domiciliary visits between June 1, 1949, and May 31, 1950

The condition of some of these patients was investigated because they had been on the E B S " chronic " waiting list for some time When the visits were made a few were found to have been admitted elsewhere or to have died

Disposal		*No of patients*
Admitted immediately	to St Pancras Hospital	35
Admitted subsequently		20
Awaiting admission		4
Admitted elsewhere		18
Admitted elsewhere by our arrangement		5
Outpatient and domiciliary treatment		21
Nothing needed		11
Died		10
Refused treatment		3
Total		127

We do not intend, in this paper, to analyse these results at any length Two interesting points, however, may be mentioned Of the 55 patients admitted after being seen in their homes, 7 had conditions which we think might have been prevented by earlier medical treatment at home If these 7 patients had seen a doctor earlier they would not have reached the state of neglect which finally necessitated their admission to hospital Moreover, a further 0 patients need not have come into hospital if better social services—such as the provision of night sitters in, more domestic help, and a laundry service—had been available Another 4 patients were admitted while aged relatives on whom they were dependent were themselves undergoing hospital tre ment We should also like to emphasise that in no c was a patient's admission to hospital refused when medical condition was so serious as to demand it

Further Development of the Service

In order to prevent such states of affairs, and improve the geriatric service, Dr D H Geffen, me officer of health of the borough, has started a St Panc Association for the Care of the Aged A club for people has also been formed, which a doctor from hospital is to attend, so that those who seek med advice can readily obtain it Welfare workers visit old people who are incapacitated in their hom especially those living alone At the same time th will be a close link with the geriatric outpatient depa ment and the outpatient services of the hospital. Th measures, it is hoped, will ensure that the plight many old people will become known to the medi authorities earlier, and granny will not be found to ha " gone " while waiting for a hospital bed to be fou for her

We wish to acknowledge with gratitude the coöperation have received in our work from Dr D H Geffen, and fr Major F Hannan of the Emergency Bed Service

MORTALITY FROM CIRCULATORY DISEASES IN NORWAY 1940–1945

Axel Strøm
M D Oslo
PROFESSOR OF HYGIENE

R Adelsten Jensen
M D Oslo
ASSISTANT PHYSICIAN, INSTITUTE OF HYGIENE

UNIVERSITY OF OSLO

In recent decades the proportion of deaths attribut to diseases of the circulatory system has increa greatly, and in civilised communities this group diseases is now the most important cause of dea Some of this increase is certainly more apparent th real, owing to the greater average length of life, mo attendance on doctors, and more accurate diagnos and there may have been some shift in diagnoses fro other groups to the circulatory group (Moriyam 1948, Woolsey and Moriyama 1948) But the possibil that there may *also* be a *true* rise in the mortality fr this group of diseases, and notably from diseases of t coronary arteries, cannot be dismissed

One explanation of the supposed increase in prevalen of these diseases is that this is connected with an increa consumption of foods containing fats and cholester If this is proved correct, ideas both on treatment a on the composition of an optimal dietary will profoundly affected

SCOPE OF INVESTIGATION

During the late war national dietaries were great changed in most European countries occupied by t enemy Food became scarce, and the shortage w primarily of foods containing fat and cholesterol the same time there was increased nervous stra which has also been held to provoke circulatory diseas In view of these facts we have investigated the mortali

TABLE III—MORTALITY FROM APOPLEXY, CHRONIC NEPHRITIS, AND ARTERIOSCLEROSIS PLUS CHRONIC MYOCARDITIS, IN URBAN AND RURAL AREAS IN 1938–40 AND 1943–45

Areas	Apoplexy		Chronic nephritis		Arterio sclerosis plus chronic myocarditis	
	1938–40	1943–45	1938–40	1943–45	1938–40	1943–45

Deaths per 10 000 pop per year	9 8	8 3	2 2	1 2	9 9	7 7
Relative mortality	100 0	84 6	100 0	52 5	100 0	77 7

Lacking data on the sex and age distribution of the population in urban and rural areas, we have been obliged to limit our further comparisons to Oslo on the one hand and the whole of Norway on the other In Oslo before the war, the adjustment of the dietary to modern standards, with a plentiful supply of "protective" foods, was fairly far advanced , and the war time food restrictions were more severe in this city than in the country as a whole Table IV shows that, for both sexes and for all ages combined, the decline was somewhat *smaller* in Oslo than in the whole country This is not in keeping with the hypothesis that food restrictions lessened mortality , but close study of the table shows that the comparatively small decline in Oslo was chiefly among women aged 80 and over Among younger women and among men in all age groups, the decline was greater in Oslo than in the whole country, and we are tempted to ask Was not the factor responsible for the decline in mortality really more effective in Oslo than in the country as a whole, this feature being obscured by more accurate diagnoses in Oslo during the later years in the case of the oldest women ?

Comparing the causes of death, one by one, we find that the mortality from apoplexy and chronic nephritis declined somewhat less in Oslo than in the whole country, whereas mortality from arteriosclerosis plus chronic myocarditis declined almost equally in the two areas However, under the age of 80 the decline in mortality from arteriosclerosis and myocarditis was greater in Oslo than in all Norway Here again, the over-80 age group forces up the total figure for Oslo, and we must again ask whether more accurate diagnosis in this age group during the later years did not play a part, camouflaging a decline

TABLE IV—MORTALITY FROM CIRCULATORY DISEASES IN ALL NORWAY AND IN OSLO IN 1943–45 RELATED TO MORTALITY IN 1938–40 WHICH IS EXPRESSED AS 100

Age (yr)	Men		Women		Both sexes	
	All Norway	Oslo	All Norway	Oslo	All Norway	Oslo
40–59	80 9	68 1	73 0	54 7	76 2	63 1
60–79	77 6	66 8	75 7	76 5	76 9	72 1
80 +	87 8	85 0	91 3	107 3	88 9	99 5
All ages						
Direct calculation	83 3	81 1	83 8	90 4	83 4	86 5
Standardised calculation	78 7	75 4	78 6	84 5	78 6	81 1

The standard population is that of Norway in 1940 The direct calculation is computed from crude death rates and the standardised calculation from the standardised death rates

CONCLUSION

More definite conclusions are impossible Our investigations have yielded, not certain proof, but several pieces of evidence for the dietary hypothesis We have, moreover, been unable to find an alternative explanation of this remarkable decline

SUMMARY

Before the late war mortality from diseases of the circulatory system was rising each year in Norway This rise ceased during the war, and from 1941 to 1943–45 there was a well marked fall in mortality from these diseases Since the war there has been a rapid rise in mortality towards the pre war level

The war time decline in mortality was equally evident for both sexes and all ages , and it involved all the most important causes of death from circulatory diseases This also applies to the post war rise

The war time decline coincided with severe dietary restrictions The supply of calories was reduced, and this reduction was principally of foods containing fat, including those rich in cholesterol

LATERALLY PLACED CERVICAL DISCS

REVIEW OF TWELVE CASES

MICHAEL JEFFERSON
M A , B Sc , B M Oxfd, M R C P
LECTURER IN NEUROLOGY IN THE UNIVERSITY OF BIRMINGHAM

Stookey (1928) drew attention to certain syndromes resulting from pressure on the spinal cord or its attached roots by nodular tumours taking origin from the intervertebral discs in the cervical region These tumours, which he believed were neoplastic, he designated ventral extradural chondromas Arising usually in or near the midline they impinged on the cord from its anterior surface, thereby dislocating it backwards The clinical picture was commonly one of total cord compression, though at times it resembled that of the Brown Séquard syndrome Very rarely the tumour might be placed so far laterally as to damage nerve roots while leaving the cord unharmed

Earlier workers had described such tumours under different titles, such as chondromata, fibrochondromata, osteochondromata, enchondromata, chondrochordomata, and so on For example, Gowers (1886), discussing compression of the spinal cord, refers to enchondroma "springing from the bones or intervertebral tissues" as a possible cause, and Oppenheim (1911) mentions just such a case, in which a spinal chondroma had been removed during life More recently Elsberg (1916, 1925) and Adson (1925) reported finding a chondroma at exploratory operation in cases believed to be due to intrinsic spinal neoplasms

Following Stookey's (1928) paper, other reports soon began to appear Elsberg (1931) stated that he had found ventral extradural chondromata in 15 cases out of 200 explored for spinal tumour He drew attention to the important work of Schmorl (1929) and Andrae (1929) on the pathological anatomy of the intervertebral discs, and commented on the close histological resemblance between the ventral chondromata and intervertebral discs He felt nevertheless that there was not a complete identity, for the former showed unmistakable hyperplasia and in that sense were to be regarded as neoplasms, though of admittedly limited activity Bucy (1930) and Alpers et al (1933) had also taken them to be true neoplasms, but it shortly came to be widely accepted

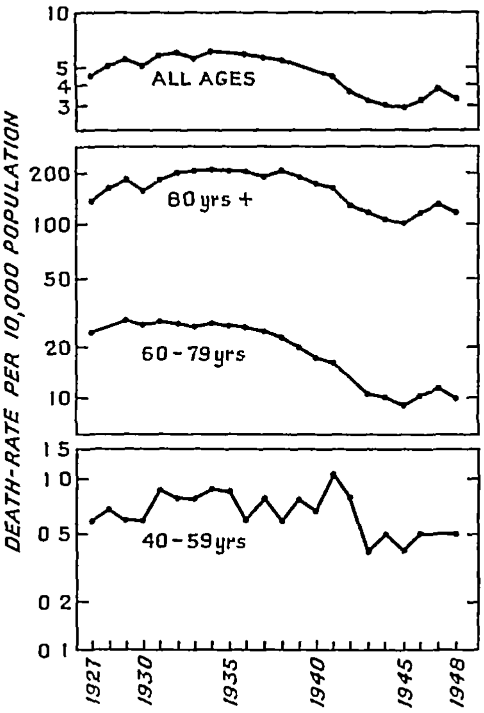

Fig 2—Mortality from arteriosclerosis in Norway in 1927-48, by age-groups

The following conclusions can be drawn

1. During the war one or more factors brought about a definite decline in mortality from diseases of the circulatory system in Norway These factors have in the main not operated since the war, and mortality has again risen
2. These factors affected all the most important causes of death from circulatory diseases, for both sexes and every age group

CHANGES IN DIET

It is natural to seek a solution in the dietary changes, which began before mortality from circulatory diseases started to decline Comparison of the dietaries of working class families in Oslo before and during the war (Strøm 1948) shows that during the war there was a considerable decline in the consumption of meat and meat products, whole milk, cream, margarine and other fats (but not butter), cheese, eggs, fruit and berries, sugar, and coffee On the other hand, there was a rise in the consumption of fish, skimmed milk, cereals, potatoes and vegetables The average calorie content of the food eaten fell from 3470 per man value per day in 1936-3 to 2850 in 1942-45 This led to widespread loss of weight The calorie reduction was chiefly in the fat component, which fell from 159 to 71 g per day, and the cholesterol content was reduced accordingly The average protein content of the diet fell from 115 to 93 g per day, while the consumption of carbohydrates rose from 395 to 429 g

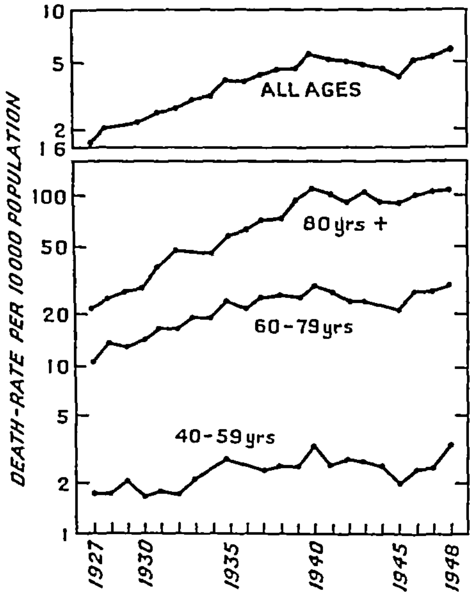

Fig 3—Mortality from chronic myocarditis in Norway in 1927 48 by age-groups.

We have obtained from the ministry of supplies data on the estimated annual consumption between 193 and 1948 of the main sources of cholesterol—milk, cream, butter, cheese, and eggs These figures are approximate, but, as fig 4 shows, there is close correlation between the curve for consumption of fat contained in these foods and the curve for mortality from circulatory diseases, with correction for age We must, however, beware of regarding this evidence as decisive Similar correlation could undoubtedly be demonstrated between mortality and trends in other commodities, such as sugar, coffee, tobacco, textiles, and footwear, yet the last two of these can hardly have exerted any influence on mortality

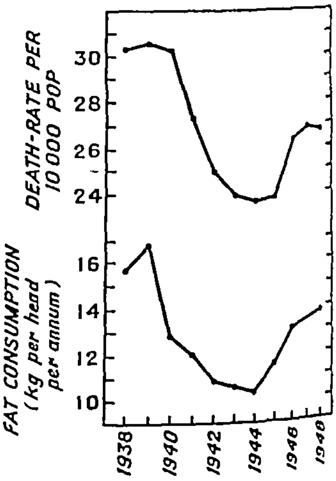

Fig 4—Mortality from circulatory diseases, corrected for age, consumption of fat in form of butter, milk cheese and eggs

TOWN AND COUNTRY

If the changes in the dietary account for the lessened mortality, the decline should be greater in urban than in rural areas The food restrictions, though applying throughout the country, made themselves felt most in the towns Indeed, in some rural areas the diet of the population improved during the war, because the farmers consumed more of their own produce

To our surprise we found that the mortality declined just as much in the rural as in the urban areas In the period 1938–40 the mortality in the urban areas was 33 5 per 10,000 population, while in the rural areas 28 6 The corresponding figures for 1943–45 were 26 9 and 23 3 Expressing mortality in 1938–40 as 100, in 1943–45 it was 80 3 in the urban areas and 81 5 in the rural areas—an insignificant difference between the two areas

However, comparison of the behaviour of each cause of death in town and in country gives a different result. Table III shows that mortality from apoplexy declined somewhat less in the urban than in the rural areas, while mortality from chronic nephritis declined about equally in the two areas, but mortality from arteriosclerosis and chronic myocarditis (combined because of the change in nomenclature) fell much more in town than in country Expressing the mortality from these two diseases in 1938–40 as 100, in 1943–45 it was 69 4 in the urban areas and 77 7 in the rural areas It is precisely these diseases that might decrease most with reduction in the supply of fats and cholesterol

FUNCTION OF ERECTORES SPINÆ IN FLEXION OF THE TRUNK

W F Floyd
B Sc Lond, F.Inst.P, A.M I E.E
SENIOR LECTURER IN PHYSIOLOGY

P H S Silver
M.B Lond
SENIOR DEMONSTRATOR OF ANATOMY

MIDDLESEX HOSPITAL MEDICAL SCHOOL, LONDON

Fick (1911) believed that the erectores spinæ relax when the vertebral column is fully flexed This means that when a man is bending down to the ground or sitting with a "round back"—both positions in which the vertebral column is in full flexion—the attitude of his spine is maintained by the ligaments and not by activity in his erectores spinæ At that time Fick's hypothesis was not supported by any experimental evidence, but the technique of electromyography has made it possible to study the action of the spinal muscles in a normal man, and we are now reporting some relevant electromyographic findings

METHOD

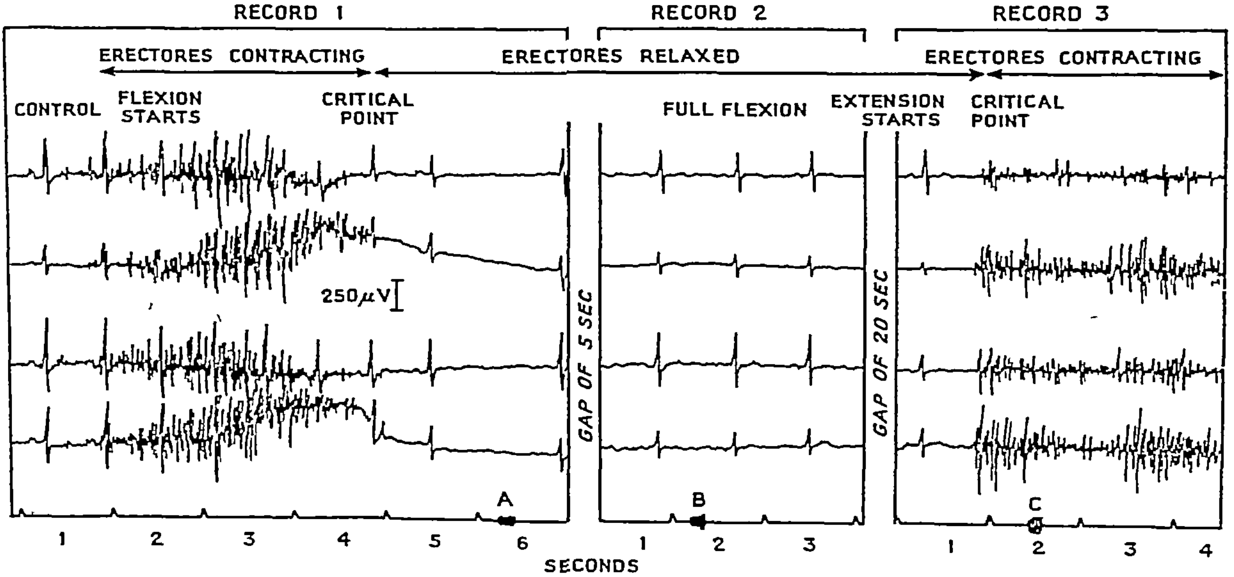
A six channel amplifier with ink-writing oscillographs was used (standard Ediswan electro encephalograph) and surface electrodes The method is painless and does not disturb the muscle in any way With this apparatus the action of three parts of the two erectores could be recorded simultaneously

When the upper parts of the erectores are studied the trapezius, rhomboids, &c, interfere with the record, unless special precautions are taken Nevertheless we have some evidence to show that the upper part of the muscle in the thoracic region behaves in the same manner as the lumbar part The lower thoracic and lumbar parts of the muscle are simpler to study experimentally, and the thoracolumbar region, being the most mobile part of the trunk, is the part most commonly injured and of special clinical interest

The electrodes were concave silver plates 1 cm in diameter, and were held in position with adhesive plaster on the skin over the erectores at the levels of the spines T10, T12, L2, and L4 When the muscle is in action, the sum of the motor unit action potentials in the vicinity is picked up by the electrodes and appears as a complex deflection on the recording pens This is a modification of the method of Floyd and Silver (1950) Deeper parts of the muscles were investigated with needle electrodes and cathode ray tube recording, but the findings were similar to those demonstrated with surface electrodes We have failed to demonstrate activity in the deep parts of the erectores—e g, in the multifidi—when the surface electrodes fail to show activity

RESULTS

The results of this study are summarised in the accompanying figure, which shows a simultaneous recording on four channels, the upper two from the left, and the lower two from the right erector spinæ All records are interrupted by the electrocardiographic complex, which is always present in electromyographic records of the trunk



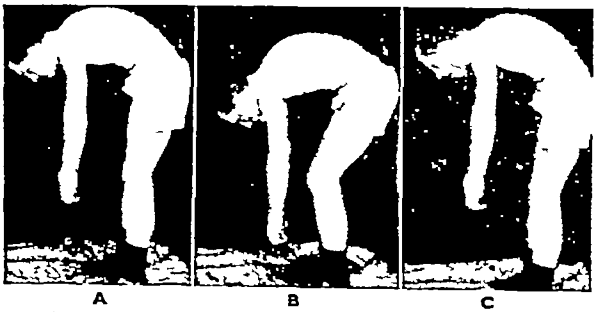
Electromyographic pattern of activity for thoracolumbar parts of erectores spinæ muscles. I from the left thoracolumbar region with the electrodes over the most prominent part of the erector spinæ opposite the spines of vertebræ T10 and T12. II from the left lower lumbar region with the electrodes similarly placed opposite the spines of vertebræ L2 and L4 III and IV, from corresponding areas of the right erector spinæ

Records I 2 and 3 are three excerpts from a single tracing obtained while the man bent down to the ground and up again In the intervals between records I and 2 and between records 2 and 3 the tracing was identical with record 2. The photographs were taken at the times marked A B and C on the chart.

During the control period the trunk was upright, and the erectores show minimal activity for about 1 sec. The activity increases at the beginning of sec. 2 as the man bends forwards and it continues to increase for 2 sec. By the beginning of sec. 5 the erectores are relaxed again and photograph A shows the man s position immediately after relaxation

When the man remains bent down to the ground (photograph B) relaxation continues as shown in record 2. The contour of the back in photographs A and B is the same only the position of hips and knees is altered

The electrocardiographic complex occurs in all three records and is especially obvious in record 2 where there is no muscular activity



A
B
C

Record 3 shows that the erectores suddenly become active again when the trunk is raised Note that the erectores are not activated at the initiation of this movement only the hips extend Photograph C shows the man s position immediately after the erectores were reactivated ; note the general similarity with photograph A.

defects that seem only the more genuine by conforming to the expected boundaries In my opinion sensory changes are almost always restricted to a slight diminution of acuity of pinprick and two point discrimination on the palmar surface only of the digital phalanges, which are the seat of subjective dysæsthesia, the rest of the dermatome area appears normal with ordinary clinical tests As regards the arm reflexes there is so much personal variety in their major segmental innervation that again no absolute constancy is found It is undoubtedly true that depression or abolition of the triceps jerk most often indicates a lesion of C7 root, and that the supinator and biceps jerks are impaired with lesions of C6 root However, the triceps reflex can be implicated at times with affections of either C6 or D1 rootlets, conversely, the supinator and the biceps reflexes may be altered by lesions of the C7 root

Straight radiography of the cervical spine in patients with radicular neuralgic complaints is not always helpful or reliable. Many apparently normal people over the age of 40 show radiological proof of degenerative arthritis in the neck (Davies 1945) These changes are usually most evident in the lower cervical spine, commonly from the level of C5 vertebral body downwards There is narrowing, often considerable, of the intervertebral disc (as seen in the lateral projection) at one or more of the interspaces C5–6, C6–7, and C7–D1, and the margins of the vertebral bodies adjacent to the affected space show sclerosis, with or without osteophytes Alternatively, in some cases the proliferative marginal changes are very pronounced, while loss of disc space is minimal or even absent In either group, however, the radiological appearances strongly suggest a pathological state of the relevant intervertebral discs The fact that the patients are symptom free is simply confirmation in the living of Schmorl's necropsy demonstration of the frequency of symptomless rupture of an intervertebral disc Conversely it is well known that the absence of radiological signs in the neck cannot be taken to mean that the intervertebral discs are healthy (Hanflig 1936, Spurling and Scoville 1944, Davies 1945) It follows that hypertrophic changes, even when associated with the grossest reduction of an interspace, in a patient with symptoms of segmental brachial neuralgia may be merely coincidental and do not necessarily define the level of the protrusion In the present cases 2 patients gave normal cervical radiograms, yet 1 of these was proved at operation to have a large disc protrusion at C5–6, and the other had clinical signs of prolapse at C6–7 Of the 10 remaining patients 7 had abnormalities at a single interspace, and 3 at two interspaces, in only 6 did the radiological signs coincide exactly with the level of root compression as determined clinically, myelographically, or operatively

Treatment

That effective treatment of segmental arm pain due to prolapsed disc is possible by simple measures is widely recognised but has recently been a little obscured by the flood of papers on its surgical cure The most generally useful method of treatment is plaster immobilisation of the neck, the cast being designed to include the head and upper chest to ensure really strict immobilisation Symptoms are almost invariably relieved by this procedure, sometimes with the most gratifying speed In the present series of cases only 1 patient had a partial relapse after removal of the collar Although he then did well with physiotherapy, such cases are often best treated by the provision of a leather collar which can be worn indefinitely Sling traction of the neck by Sayre's method has its advocates (Turner and Oppenheimer 1936, Hanflig 1943), but it means that the patient must be kept in bed lying on his back, whereas the patient in plaster can be fully ambulant and need not even remain in hospital Physiotherapy, in the form of massage, radiant heat, or diathermy with active graduated physical exercises, has a definite place in treatment where symptoms are not severe

Operation should properly be reserved for those whose symptoms are of long duration and are known to resist more modest courses of action In this context, however, it may be recalled that the morbid anatomy of protruded cervical disc often differs in some respects from that of protruded lumbar disc The lumbar nerve roots are usually injured by herniations of more or less discrete disc substance, whereas in the neck this is seldom so More often, as Elsberg emphasised long ago, there is an accompanying bony and fibrocartilaginous proliferation, arising from the margins of the vertebral bodies and from the annulus fibrosus, which may be the major element in causing stretching or compression of the nerve root From the surgical point of view it can be far more difficult, technically, to remove such a secondary tumefaction adequately, than to ablate the extruded disc matter itself Thus decompression of the root may perforce be incomplete, or transient, for there is no guarantee that further proliferation will not take place postoperatively Unfortunately it is impossible to gauge, before exploration, how far root damage is due to one factor rather than to the other These facts in themselves may be taken as an argument against too hasty recourse to surgery

Finally it has to be admitted that, although surgical treatment carries no more than the usual anæsthetic risk to life, operation does bring with it a small but definite hazard to the spinal cord, as Michelsen has pointed out, and as 1 of the 4 cases submitted to surgery in this series bears witness

SUMMARY

A brief historical introduction to the subject of cervical disc prolapse is given

The main features of 12 cases with radicular brachial neuralgia from lateral disc prolapse are summarised, their treatment indicated, and illustrative examples given

The levels of disc protrusion are discussed, the symptoms and signs of involvement of various radicles are considered, and the usefulness of radiological findings assessed

A plea for conservative treatment is entered

My thanks are due to Professor Cloake for allowing me to re-examine and make observations on his patients

SENIOR DEMONSTRATOR OF ANATOMY

MIDDLESEX HOSPITAL MEDICAL SCHOOL, LONDON

Fick (1911) believed that the erectores spinæ relax when the vertebral column is fully flexed This means that when a man is bending down to the ground or sitting with a "round back"—both positions in which the vertebral column is in full flexion—the attitude of his spine is maintained by the ligaments and not by activity in his erectores spinæ At that time Fick's hypothesis was not supported by any experimental evidence, but the technique of electromyography has made it possible to study the action of the spinal muscles in a normal man, and we are now reporting some relevant electromyographic findings

METHOD

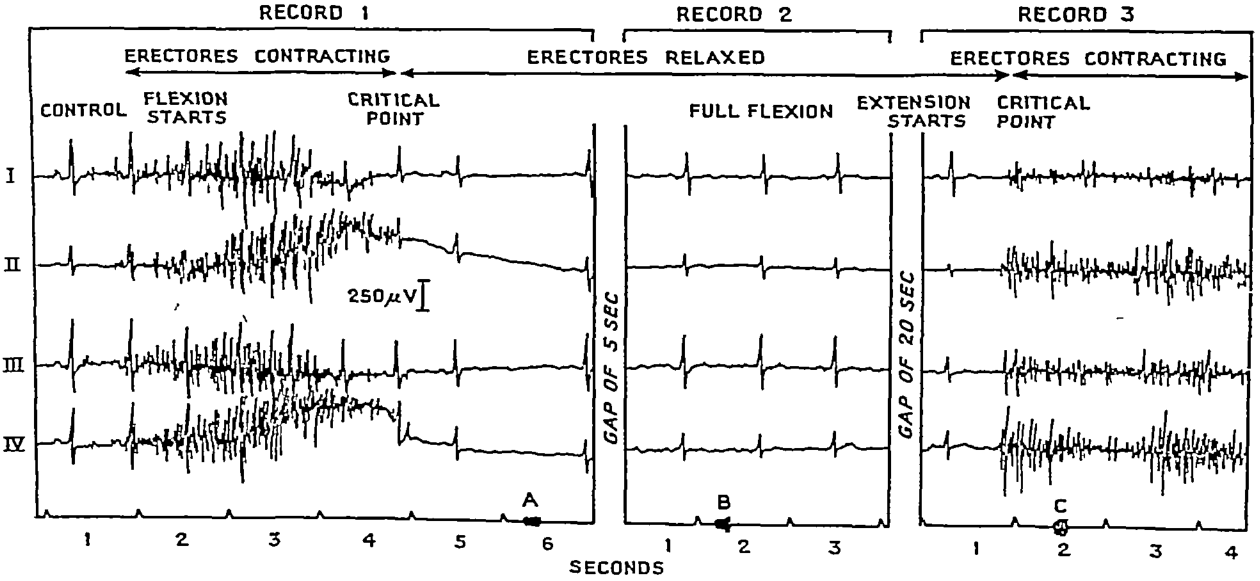
A six channel amplifier with ink-writing oscillographs was used (standard Ediswan electro encephalograph) and urface electrodes The method is painless and does not listurb the muscle in any way With this apparatus he action of three parts of the two erectores could be ecorded simultaneously

When the upper parts of the erectores are studied the trapezius, rhomboids, &c, interfere with the record, unless special precautions are taken Nevertheless we have some evidence to show that the upper part of the muscle in the thoracic region behaves in the same manner as the lumbar part The lower thoracic and lumbar parts of the muscle are simpler to study experimentally, and the thoracolumbar region, being the most mobile part of the trunk, is the part most commonly injured and of special clinical interest

The electrodes were concave silver plates 1 cm in diameter, and were held in position with adhesive plaster on the skin over the erectores at the levels of the spines T10, T12, L2, and L4 When the muscle is in action, the sum of the motor unit action potentials in the vicinity is picked up by the electrodes and appears as a complex deflection on the recording pens This is a modification of the method of Floyd and Silver (1950) Deeper parts of the muscles were investigated with needle electrodes and cathode ray tube recording, but the findings were similar to those demonstrated with surface electrodes We have failed to demonstrate activity in the deep parts of the erectores—e g, in the multifidi—when the surface electrodes fail to show activity

RESULTS

The results of this study are summarised in the accompanying figure, which shows a simultaneous recording on four channels, the upper two from the left, and the lower two from the right erector spinæ All records are interrupted by the electrocardiographic complex, which is always present in electromyographic records of the trunk



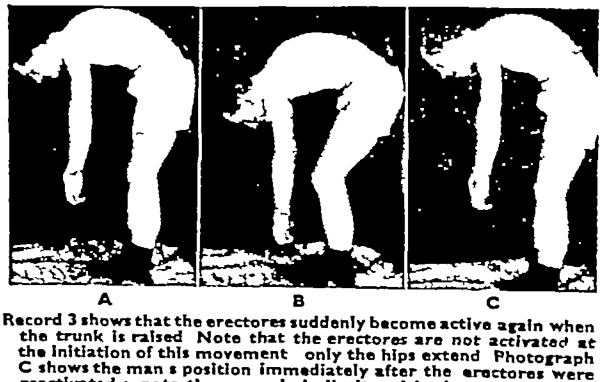
Electromyographic pattern of activity for thoracolumbar parts of erectores spinæ muscles I from the left thoracolumbar region with the electrodes over the most prominent part of the erector spinæ opposite the spines of vertebræ T10 and T12. II from the left lower lumbar region with the electrodes similarly placed opposite the spines of vertebræ L2 and L4 III and IV, from corresponding areas of the right erector spinæ

Records 1 2 and 3 are three excerpts from a single tracing obtained while the man bent down to the ground and up again In the intervals between records 1 and 2 and between records 2 and 3 the tracing was identical with record 2. The photographs were taken at the times marked A B and C on the chart.

During the control period the trunk was upright, and the erectores show minimal activity for about 1 sec. The activity increases at the beginning of sec. 2 as the man bends forwards and it continues to increase for 2 sec. By the beginning of sec. 5 the erectores are relaxed again and photograph A shows the man's position immediately after relaxation

When the man remains bent down to the ground (photograph B) relaxation continues as shown in record 2. The contour of the back in photographs A and B is the same; only the position of hips and knees is altered

The electrocardiographic complex occurs in all three records and is especially obvious in record 2 where there is no muscular activity



Record 3 shows that the erectores suddenly become active again when the trunk is raised Note that the erectores are not activated at the initiation of this movement only the hips extend Photograph C shows the man's position immediately after the erectores were reactivated; note the general similarity with photograph A.

During the 1st sec of record 1 the man was standing upright, and the trace shows minimal activity in the erectores About 1 sec from the beginning of the record the man began to bend forwards, and the vertebral column and hip joints began to flex The activity in the erectores increased considerably for about 2 sec as the man leaned further and further forwards, and the muscles acted as anti gravity muscles to prevent the trunk from falling forwards By the beginning of the 5th sec of record 1 the erectores relaxed once more, in spite of the fact that the man was leaning forwards The photograph A, to show the position of the trunk when the erectores were relaxed, was taken at the moment shown by the signal mark A in record 1, and this photograph shows approximately the critical position for relaxation of the erectores spinæ in this man when leaning forward The spine was now fully flexed, and the erectores were relaxed and no longer acted as anti-gravity muscles Their function, that of maintaining the position of the flexed spine, must therefore have been taken over by non contractile tissue Bending further downwards was achieved only by flexing the hip joints photograph B, taken at signal mark B in record 2 shows that the attitude of the back was unchanged, but the hips were more flexed than in photograph A, and the erectores were still inactive

When the man began to raise himself again to the upright position, the movement began by an extension of the hip joints During this phase of the movement, the last part of which is shown in the 1st sec of record 3, there was no activity in the erectores At the beginning of the 2nd sec, however, the erectores became active again Photograph C, taken at signal mark C in record 3, shows the man's position approximately at this moment when the erectores contracted The activity in the erectores continued until the man once more returned to the upright position Note the similarity between photographs A and C

DISCUSSION

It is known that posture is maintained by muscle action and that the function of ligaments is to limit the extremes of movement (Wiles 1935, 1937, 1949) During the initial stages of trunk flexion in standing the movement is controlled by the erectores spinæ, but, when the fully flexed position is reached, the ligaments alone are concerned with maintaining the position

In the position of full flexion in sitting—Andry's (1743) "bad posture"—the electromyographic studies show that the erectores are relaxed This position is often maintained comfortably for a relatively long time compared with the discomfort from a fully extended knee joint which becomes painful within a few minutes This difference we attribute to the presence of the elastic ligamenta flava in the spine, and we regard this phenomenon not as an exception to the generally accepted ideas about the ability of ligaments to stand strain indefinitely but as a special case in view of the presence of the specialised elastic ligaments However, we do not suggest that this position can be maintained indefinitely without discomfort, because certain people experience backache if they sit in the fully flexed position for a sufficient time—e g, patients sitting in bed with only the thoracic part of the vertebral column supported, motor car drivers, &c

Presumably stretch receptors in the ligamenta flava and other ligaments are stimulated when these ligaments are stretched, and the afferent impulses from the stretch receptors cause reflex inhibition of the erectores spinæ We do not at present possess a suitable laboratory animal for studying this reflex in detail, and have no direct experimental evidence to support this hypothesis For this reason, at present, we prefer to speak of the relaxation' rather than the reflex inhibition" of the erectores Such a reflex inhibitory mechanism, however, seems the most likely explanation

The phenomenon can be useful clinically in differentiating back pain originating in muscle and back pain originating in ligaments If a patient with pain in th back can be persuaded to bend to the fully flexed position pain from ligaments should get progressively worse whereas pain from muscle should improve (but wil not necessarily disappear altogether) This has bee demonstrated clinically in some cases

The main interest, however, lies in the insight which we now have into the mechanism of injury to the annulu fibrosus This injury often occurs when the spine i flexed (Wiles 1949) In this position the strain of th trunk falls on the ligaments Owing to mechanical factor tensions of about 1500 lb (Bradford and Spurling 194 operate on these ligaments, plus any additional loa which is being carried The erectores spinæ do not shar in bearing the load The strain falls on the elast ligamenta flava and the other less elastic ligament including the annulus fibrosus These relatively inelast structures are most easily damaged Hence injury ca result in apparently trivial circumstances—e g, tying shoe lace (Jackson 1950) The patient need not hav been lifting or lowering a weight (apart from h body weight)

The relaxation of the erectores spinæ in the full flexed position is in no sense "the cause" of ruptur of the annulus fibrosus, it is only a contributory facto which can operate only in the circumstances described

SUMMARY

Observations are described which show that ful flexion of the spine is accompanied by relaxation of th erectores spinæ Consequently in this position furthe flexion is limited only by the intervertebral ligament It is thought that there are limits to the time for whic the ligaments can support this tension—e g, in sittin —just as there are limits to the tension which th ligaments can withstand in weight lifting

Some clinical implications are described in backach and the mechanism of rupture of the annulus fibrosus

THIOURACIL COMPOUNDS IN THE PREVENTION OF PAROXYSMAL CARDIAC ARRHYTHMIA

H D Ruskin
M B Witwatersrand, M R C P
MEDICAL REGISTRAR, JOHANNESBURG GENERAL HOSPITAL, A
CONSULTING PHYSICIAN, KRUGERSDORP HOSPITAL, TRANSVA

MANY drugs and manœuvres are advocated for termin ting a paroxysm of cardiac arrhythmia, but there a few methods of preventing such attacks Of these t best known are the administration of quinidine an digitalis (Linenthal and Freedberg 1949), dehydratio (Gold 1948), and sympathetic denervation (White a Smithwick 1941) Not uncommonly these measur fail, and, with quinidine, problems of dosage an toxicity may arise

Because thiouracil compounds are effective in th control of angina pectoris, and because the factors whic precipitate attacks of angina and the paroxysmal cardia arrhythmias are mainly identical, I thought that the drugs might prove of value in preventing the latter. Since October, 1949, thiouracil derivatives have been administered to seven patients, in all of whom previous treatment with quinidine and digitalis had been unsatisfactory, because it failed or caused untoward reactions. Four of these patients were women and three were men, their ages varying from 22 to 67 years. The frequency of the attacks varied greatly: in four cases these were a daily occurrence; in two cases there were several bouts each week; and in one case several each month. One patient was admitted to hospital because of the severity of the attacks, whereas the remainder were treated as outpatients.

Of the seven patients, two had apparently normal hearts, three had hypertensive heart disease, and two had rheumatic valvular disease. None showed evidence of thyrotoxicosis. Electrocardiographic proof of the arrhythmia was obtained in six cases: three had supraventricular tachycardia, two auricular flutter with auriculo-ventricular block, and two auricular fibrillation.

CASE REPORTS

Case 1.—A married woman, aged 60, was admitted to the Johannesburg Hospital on July 18, 1949, complaining of attacks of palpitation and breathlessness of 8 years' duration, which had become more severe and more frequent in the past few months, when they had been lasting for hours or even days. They were usually precipitated by exertion and by emotional disturbance.

The patient was very obese and distinctly cyanosed; pulse-rate 200 per min., and blood-pressure (B.P.) 170/110 mm. Hg. The electrocardiogram showed auricular flutter with 2 : 1 auriculo-ventricular block. The attack was terminated in 6 hours by means of gr. $^{1}/_{4}$ of morphine and gr. 6 of quinidine orally every 2 hours. Despite continued administration of gr. 6 of quinidine at 8-hourly intervals 2 days later she had a further paroxysm, with a ventricular rate of 140 per min. Digitalisation (digoxin 1 mg. intravenously, followed by 0.25 mg. daily by mouth), combined with gr. 3 of quinidine 3-hourly and later 2-hourly, did not prevent the paroxysms, which recurred with a ventricular rate varying from 140 to 220 per min. During some of the attacks she became extremely dyspnœic and cyanosed, with a fall of B.P. to 80/60 mm. Hg; and on several occasions when the attack had continued for more than 6 hours, congestive cardiac failure developed, necessitating strict salt restriction and the administration of mercurial diuretics. Additional remedies, such as intravenous procaine, aminophylline, and 'Neosynephrin,' were tried at different times in an attempt to terminate the more severe attacks; but gr. 3 of quinidine intravenously proved the most effective.

Between paroxysms the pulse-rate was 80 per min. and the B.P. 180/110 mm. Hg; the electrocardiogram revealed a normal rhythm with evidence suggestive of left ventricular hypertrophy. Radiologically the heart was enlarged with a hypertensive configuration.

On Oct. 10 treatment with methyl thiouracil—0.6 g. daily in three divided doses—was begun, while the patient continued to take gr. 6 of quinidine at 4-hourly intervals. Except for one mild attack, on the second day of this treatment there followed a period of freedom from attacks which lasted almost 3 months, the patient becoming ambulatory within a fortnight after having been bedridden for 8 weeks. The dose of quinidine was decreased until it was finally discontinued at the end of one month. The basal metabolic rate shortly after the start of treatment with methyl thiouracil was + 28%.

After her discharge from hospital on Dec. 2 the patient remained free of attacks until Dec. 23, when she was frightened by a flash of lightning and immediately developed a paroxysm. Several further attacks occurred during an emotional crisis occasioned by the sudden illness of her husband.

She was readmitted to hospital on Jan. 6, 1950. While taking methyl thiouracil, she continued to have mild bouts which were terminated promptly by quinidine intravenously in gr. 3 doses. The basal metabolic rate on Jan. 16 was +25% and the blood-cholesterol 270 mg. per 100 ml. The electrocardiographic pattern recorded during paroxysms was the same as before. Propyl thiouracil—0.6 g. and later 1.2 g. daily—was substituted for the methyl preparation. The attacks became still less frequent and more readily controlled by intravenous quinidine. On March 10, the daily dose of propyl thiouracil was reduced to 0.6 g. in three divided doses, and gr. 6 of quinidine was added to each dose. Since then the attacks have become infrequent and less severe, each responding promptly to gr. 3 of quinidine intravenously.

After administration of methyl thiouracil this patient, previously completely incapacitated and at times dangerously ill, was able to lead a comparatively normal life. While she is still not entirely free of paroxysms, they are now infrequent, mild, and easily controlled.

Case 2.—A 36-year-old housewife first consulted me in November, 1948, with a 28-year history of paroxysmal tachycardia. During the past few years the attacks, which had been occurring almost daily, were usually short and were often terminated by deep breathing or drinking iced water. They were usually precipitated by physical exertion or emotional stress and were more prone to come on before and during menses. Throughout her first pregnancy in 1947 she was completely free of attacks.

The patient was a well-developed, apprehensive young woman with no demonstrable cardiovascular abnormality other than persistent tachycardia at a rate of 100 per min. There was no clinical evidence of thyrotoxicosis and repeated basal metabolic rate determinations were normal. The B.P. was 130/80 mm. Hg, and radiologically the cardiac shadow was normal. An electrocardiogram obtained during an attack in 1945 showed supraventricular tachycardia at a rate of 160 per min. Between paroxysms, at rest and after exercise, the electrocardiogram was normal.

One year later—in 1949—her condition was unchanged. Treatment with propyl thiouracil in a daily dosage of 0.6 g., given in three divided doses, was started, and within a week the bouts of palpitation had ceased. After 8 weeks, owing to the severe nausea and vomiting of pregnancy, she discontinued the drug; and she then had a further four severe attacks within 2 weeks. On recommencing the drug the attacks again ceased. Because during a previous pregnancy she had been completely free from attacks it was decided to exclude the present pregnancy as the cause of her recent improvement. The drug was therefore again discontinued, but within 10 days there was an unusually severe attack lasting twenty-four hours followed by a series of shorter bouts at brief intervals. Within 5 days of recommencing propyl thiouracil in the daily dosage of 0.3 g., the paroxysms again ceased completely and have not recurred.

The prompt and complete control of the frequent paroxysms while taking propyl thiouracil, and their early recurrence on discontinuing the drug, are noteworthy features in this case.

Case 3.—A moderately obese 50-year-old man had been experiencing occasional attacks of palpitation for 7 years until 3 years ago when he began to have three or four attacks each week. The paroxysms, each lasting 6–8 hours, occurred usually at night when he was tired or worried, and could usually be terminated within a few hours by gr. 6 of quinidine.

In 1948 no clinical evidence of cardiovascular disease was found, the resting pulse-rate being 72 per min. and the B.P. 130/90 mm. Hg. Radiologically the cardiac shadow was normal; and the basal metabolic rate was – 5%. The electrocardiogram was normal at rest and after exercise, but during a paroxysm it showed auricular fibrillation. Quinidine in doses of gr. 6 thrice daily failed to prevent the attacks, and increase in the dosage was impracticable as it caused diarrhœa. Digitalis likewise proved ineffective.

In November, 1949, the paroxysms were occurring every night. Methyl thiouracil treatment was started with 0.6 g. daily in three divided doses. No improvement was noted after one month, so gr. 6 of quinidine was given with each dose of methyl thiouracil. The attacks ceased promptly. Propyl thiouracil was substituted for methyl thiouracil in the same dosage and quinidine was omitted; but the nocturnal paroxysms returned within a few days. Next, the total daily dose of propyl thiouracil was given at bedtime but no improvement ensued; so a single combined dose of 0.3 g. of propyl thiouracil with gr. 6 of quinidine was given at night. On this régime the attacks soon became fewer and shorter; but because paroxysms began to occur also during the daytime, 0.2 g. of propyl thiouracil was given with gr. 6 of quinidine every 8 hours; and within a few days the attacks ceased except for an occasional mild paroxysm.

This case demonstrates the value of the use of thiouracil together with quinidine for the control of paroxysmal auricular fibrillation, where neither alone has proved effective

Case 4 —A 22 year old man, a university student, was seen in 1947 because of infrequent attacks of rapid heart action, of one year s duration, each bout lasting 6–12 hours He had had three attacks of rheumatic fever Clinical and radiological examination revealed gross cardiac enlargement with mitral stenosis and aortic incompetence The resting pulse rate was 80 per min , and the B P 120/70 mm Hg Between attacks the electrocardiogram was normal except for the presence of mitral P waves The paroxysms were relieved by the administration of gr 9 of quinidine daily During the ensuing months, the attacks became more frequent and severe , and in 1948, despite gr 18 of quinidine daily, he was experiencing weekly paroxysms with a regular rhythm and a rate varying from 130 to 180 per min To induce dehydration supplementary therapy was instituted with ammonium chloride, mercurial diuretics and salt restriction , but these had no effect

During 1949, his condition deteriorated despite digitalisation and the daily administration of gr 30 of quinidine, two attacks of arrhythmia were occurring each week These attacks were longer persisting for 6–12 hours, and were terminated only after three or four doses of gr 9 of quinidine had been taken at hourly intervals Invariably the omission of a single routine dose of quinidine was promptly followed by a paroxysm which was sometimes precipitated by emotional stress or undue physical exertion Nevertheless, he had been able to lead a fairly active university life

Re examination in December, 1949, showed a further increase in the size of the heart although there were no signs of congestive cardiac failure An electrocardiogram during an attack showed auricular flutter (auricular rate 240, ventricular rate 90 per min) with a varying auriculo ventricular block resulting in a very irregular pulse

While treatment with digitalis and quinidine continued, methyl thiouracil in daily doses of 0 6 g was instituted After 2 months, there having been no diminution in the frequency or severity of the attacks, propyl thiouracil was substituted and was given at the higher dosage level of 1 0 g , and later of 1 2 g daily , but again no preventive effect was noted

This case demonstrates the failure of thiouracil derivatives to prevent attacks of auricular flutter in a patient suffering from valvular heart disease of rheumatic origin with gross cardiac enlargement

Case 5 —A 67 year old widow, first examined in July, 1946 complained of daily attacks of palpitation lasting from a few seconds up to 8 hours, which began with the menopause in 1932 She was anxious and moderately obese, with a pulse rate of 84 per min and a B P of 190/110 mm Hg No clinical evidence of thyrotoxicosis was apparent Orthodiascopic examination showed unfolding of the aorta and an increase in cardiac size due to left ventricular enlargement The electrocardiogram was normal between attacks but showed the presence of auricular fibrillation during a paroxysm

Quinidine was prescribed in a daily dosage of gr 9 and the attacks became less frequent , but because of nausea the patient would not continue to take this drug Digitalis was thereupon substituted, with subsequent improvement , but she discontinued this drug of her own accord

In 1949 chronic lymphatic leukæmia was diagnosed The paroxysmal auricular fibrillation had persisted, but the cardiovascular state had not deteriorated Propyl thiouracil —0 6 g daily—was prescribed in January, 1950 The effect was immediate, there being only one subsequent attack of fibrillation Since the leucocyte count fell rapidly from 48 000 to 24 000 per c mm , the dose of propyl thiouracil was reduced to 0 15 g daily , and thereafter she had two more paroxysms Since then she has remained completely free of bouts while taking 0 3 g of propyl thiouracil daily , and the improvement in her emotional state, in her sense of well being, and in her loss of heart consciousness has been most striking

This case demonstrates the immediate and complete inhibition of very frequent paroxysms of auricular fibrillation by means of propyl thiouracil without quinidine or digitalis

Case 6 —A 47 year old merchant presented himself in January, 1950, with the complaint that for 2 years he had suffered from attacks of racing of his heart two or three times each month, following emotional stress He experienced a sense of constriction of his chest when emotionally upset, but not on exertion Clinical examination revealed pulsus bisferiens at a rate of 80 per min with occasional extrasystoles, a blood pressure of 110/80 mm Hg, and the auscultatory signs of aortic stenosis and incompetence with mitral stenosis. On X ray screening the heart was found to be enlarged owing to hypertrophy of the left ventricle The electrocardiogram with the patient at rest showed a normal rhythm and evidence of left ventricular hypertrophy Although no changes in the S–T segment took place after exercise, the precordial constriction was regarded as anginal A tracing during a paroxysm revealed supraventricular tachycardia Treatment with digoxin had failed to influence the symptoms

Propyl thiouracil—0 6 g daily—was prescribed, and within a few days the attacks of precordial constriction after excitement ceased The patient has remained free of paroxysmal tachycardia for three months on a maintenance dose of 0·3 g of the drug daily

In this case paroxysms of arrhythmia were always infrequent , but since treatment with thiouracil was started the period of freedom from attacks has exceeded the duration of the natural intervals in the past

Case 7 —A housewife, aged 43, was seen in July, 1948, with the history that for 3 years she had suffered from bouts of palpitation lasting $^1/_2$–2 hours, each bout starting and ending suddenly The number of these attacks varied from several in a day to one in a month She appeared anxious and tremulous, the pulse rate being 96 per min and the blood pressure 180/110 mm Hg, but no signs of thyrotoxicosis were evident Screening of the heart showed prominence of the left ventricle and a normal transverse diameter An electrocardiogram obtained between attacks revealed evidence of left ventricular hypertrophy The basal metabolic rate was +14%

During the ensuing 6 months she remained moderately free of paroxysms while taking gr 9 of quinidine daily together with small doses of phenobarbitone Subsequently, after several attacks lasting 6–8 hours, the dosage of quinidine was increased to gr 15 daily She apparently discontinued treatment , and when she was again seen in February, 1950, the paroxysms were occurring three to four times each week and were lasting up to an hour The B P was 160/100 mm Hg and the electrocardiogram was unchanged , but the cardiac shadow had increased by 0 5 c m in its transverse diameter Her family doctor witnessed an attack in which the pulse-rate was 120 per min and the rhythm regular Methyl thiouracil was prescribed in the daily dosage of 0 6 g , and within a week she had become free of paroxysms except for an occasional bout lasting only a few minutes Within a few days of her discontinuing the drug, because of an intercurrent infection, the bouts recurred , but they again ceased shortly after treatment was resumed

Electrocardiographic proof of the nature of the arrhythmia was not obtained in this case, but the attacks were probably due to supraventricular tachycardia

DISCUSSION

The rôle of emotional stress in precipitating extrasystoles, paroxysmal auricular tachycardia and auricular fibrillation in individuals with normal or diseased hearts has been demonstrated by Duncan et al (1949) In each of the cases in the present study there was obvious emotional disturbance with anxiety or depression, while in several there was clear evidence of the precipitation of attacks of arrhythmia by emotional stress Emotional stimuli are thought to produce this effect through the autonomic nervous system and the endocrine glands—particularly the thyroid and adrenal (Katz et al 1947)

Circulating adrenaline increases under a variety of circumstances, prominent among which are emotional stress and physical effort , and adrenaline tends to accumulate in the myocardium, on which it has an anoxiating effect (Green et al 1942) This effect is augmented and intensified by thyroxine (Raab 1945a), while thiouracil diminishes the sensitivity of the normal heart to adrenaline (Raab 1945b) On the supposition that an excess of circulating adrenaline was responsible for precipitating attacks of angina pectoris this condition was successfully treated with thiouracil (Raab 1945c).

The rapidity with which some cases of angina pectoris or paroxysmal arrhythmia respond to treatment with thiouracil compounds, and the early relapses when such treatment is discontinued, suggest a similar mode of action of the drugs in these two conditions. Possibly thiouracil exerts a direct effect on the myocardium and its action apparently does not depend on reduction in the rate of metabolism. Where the drug proved effective the attacks were brought under control within a week, whereas where no response was noted within this period no effect was obtained from further administration of the drug.

Of the seven patients studied in the present series, six had failed to respond adequately to quinidine. In those patients that do respond to quinidine, the maintenance dose of this drug may perhaps be reduced by the addition of a thiouracil compound. Conversely, where the response to thiouracil is complete, the dosage can probably be reduced by the additional administration of quinidine.

Although this preliminary study has not definitely established the relative therapeutic value of the thiouracil compounds compared with quinidine or digitalis, further trials of the former drugs in the preventive treatment of the paroxysmal cardiac arrhythmias would appear to be warranted.

SUMMARY

Methyl and/or propyl thiouracil was administered in seven cases of paroxysmal cardiac arrhythmia.

In four the paroxysms were completely prevented , in two they became less frequent and less severe , and in one there was no response.

In two patients the combination of a thiouracil compound with quinidine was more effective than either drug alone.

It is a pleasure to record my gratitude to Dr M. M. Suzman, of Johannesburg, for his help in the preparation of this paper.

PHYSICIAN AND DIRECTOR, DEPARTMENT OF HÆMATOLOGY

MANCHESTER ROYAL INFIRMARY

SINCE the war time investigations of Wilkinson, begun in 1942, on the cytotoxic effects of β chloro alkylamines and their therapeutic value in leukæmias and reticulosis (Wilkinson and Fletcher 1947) many groups of workers have reported similar observations.

Widely different degrees of benefit have been described. In our series of over a hundred cases of chronic leukæmia, Hodgkin's disease and allied disorders treated usually with the nitrogen mustard tris β chloroethylamine hydrochloride ('HN3') intravenously, satisfactory remissions have been obtained in at least 80% of the cases (Gardikas and Wilkinson, to be published).

Since the therapeutic effects of this type of substance have been confirmed, intensive search has been made for similar compounds that might exert more effective and more prolonged effects without their general cytotoxic effects. At the same time, the greater convenience and safety in unskilled hands of substances suitable for oral administration would circumvent some of the inherent difficulties of the present intravenous treatment. Burchenal (1948) has reported his experience with two nitrogen mustard derivatives—the 1 3 propane diamine NNN'N' tetrakis (2 chloroethyl) dihydrochloride ('SK136') and the 1 3 propane diamine 2 chloro NNN'N' tetrakis (2 chloroethyl) dihydrochloride ('SK137'). Both products were tried in leukæmia but showed no advantages over the original nitrogen mustards. Craver (1948) also has reported similar negative results. Haddow et al (1948) prepared a series of aromatic nitrogen mustards, and one of these products, β naphthyl di 2 chloroethylamine ('R48'), has been subjected to clinical trials by several groups of workers under the ægis of the Medical Research Council. The present report summarises our results in this therapeutic trial. Matthews (1950) has already reported the results obtained by another group in these trials.

CLINICAL MATERIAL

Twenty five patients (eleven male and fourteen female) have been treated with R48 in this series. There were eight cases of chronic lymphatic leukæmia, five of chronic myeloid leukæmia, two of acute leukæmia, seven of Hodgkin's disease one of lymphosarcoma, one of giant follicular reticulosis, and one of mycosis fungoides. The patients were adults aged 17–69, except for one child aged 12 years.

Diagnoses of the particular diseases were made by the usual clinical and pathological observations, including marrow biopsy in all cases, gland biopsy in all cases of Hodgkin's disease lymphosarcoma and giant follicular reticulosis, and skin biopsy in the case of mycosis fungoides.

DOSAGE AND METHOD OF USE

β naphthyl di 2-chloroethylamine (R48) was given by mouth in divided doses three times daily to a total of 100–400 mg daily. In chronic leukæmia the treatment was usually continued until the white cell count had fallen to about 20,000 per c mm , unless toxic symptoms necessitated an earlier discontinuance of the treatment. In Hodgkin's disease or other reticuloses in which there was little leucocytosis before the start of the treatment, the criteria for the continuation of treatment were less rigid in view of our experience with intravenous therapy. As a rule the treatment was continued until a white cell count of about 3000–4000 per c mm was reached, or until clinical symptoms and signs—e g , lymphadenopathy—had disappeared. After preliminary trials had established a safe line of procedure, the patients, while under treatment with R48, were seen regularly at weekly or fortnightly intervals for blood-counts and clinical examination. When the initial course had been completed and remission obtained, the treatment was discontinued, the patient still being followed up at fortnightly or monthly visits and further courses being given when required. Attempts to introduce a maintenance dose in the hope that the duration of the remission could be prolonged considerably were not satisfactory, for we noted that usually a very small maintenance dose remained ineffective, whereas a larger one might produce leucopenia.

TOXIC EFFECTS

In one patient with chronic lymphatic leukæmia treatment with R48 produced gross hæmaturia necessitating a discontinuance of treatment and another patient developed a moderate dysuria with microscopical hæmaturia , but both conditions cleared completely as soon as treatment was stopped A generalised purpuric rash developed in another patient without thrombocytopenia, but cleared satisfactorily In two other cases a transient maculopapular rash was noted, but further treatment was given uneventfully In no case was there any relation between the appearance of toxic symptoms and the daily or total dose of the drug administered

RESULTS*

Acute Leukæmia

Two patients with acute leukæmia were treated with R48 One was given total doses of 6 8 g in 17 days, and the other 21 6 g in 30 days The disease followed its usual course without any symptomatic relief or objective improvement

Chronic Myeloid Leukæmia

Five cases of chronic myeloid leukæmia were treated In two cases satisfactory clinical and hæmatological remissions were obtained the white cell counts fell from 139,000 to 13,600 per c mm and from 233,000 to 16,000 per c mm , the hæmoglobin values rose moderately , the general condition improved , and the feeling of well being returned Splenomegaly regressed considerably in one patient but remained almost unaffected in the other Both patients have had repeated courses , both are alive and well with fairly good working capacity 20 and 22 months after the institution of the treatment In the third case there was no improvement, though the white cell count fell from 158,000 to 42,000 per c mm , the patient died 2 months after R48 treatment was started, but by then he had reached a very advanced stage, having received treatment previously with urethane and other agents for 30 months The fourth case was in a boy, aged 17 with 6 months' history of subjective symptoms and presenting a typical clinical and hæmatological picture of chronic myeloid leukæmia He had had no previous treatment and was given R48 300 mg daily for 30 days—a total dose of 9 g At the end of this period the lymph node and splenic enlargements remained the same and the white cell count rose from 120,000 per c mm before treatment to 290,000 per c mm Subsequent treatment with intravenous tris β chloro ethylamine produced very rapidly a good remission Another patient has had treatment for only a short time but is responding satisfactorily

Chronic Lymphatic Leukæmia

Eight cases of chronic lymphatic leukæmia were treated In two the results were satisfactory , good and long remissions were obtained, and both patients are well, with full working capacity, 22 and 20 months after the start of treatment with R48 Two other patients presented only remissions in their constitutional symptoms but no reduction of lymphadenopathy They have not yet returned to work 19 and 4 months since treatment with R48 was first given In three other patients, although the white cell counts returned to normal, the lymph node and splenic enlargements showed no changes, the anæmia did not improve, and the patients died 1, 1, and 9 months after treatment with R48 had been begun, without any apparent relief of the clinical course of the disease Another patient has had treatment for only a short time

Hodgkin's Disease

Seven patients have been treated In three the results were very good and the involved tissues regressed completely or almost completely The quantities required to produce these remissions were 5 g in 50 days, 45 g in 150 days, and 24 g in 60 days The general condition was good in all three cases and has remained good until now, 7, 20, and 24 months since treatment began Another patient was a woman of 45 who had previously been treated with intravenous tris β chloroethylamin for 2 years, which had produced such remarkably good results in this time that she had continued to run a ver busy company and had regained her well being , she ha gained so much weight as to render it very difficult to giv intravenous therapy owing to poor access to veins, an so for over 12 months now she has been maintained o R48 with good response One patient has severe Hodgkin's disease involving soft tissues and skeletal structure and has responded quite well to intravenous therap Owing to technical difficulty with her veins also, she ha been put on to R48 orally, but the response is not ver good In two other cases the treatment failed and bot patients died after having received 3 3 g in 24 days an 3 4 g in 17 days

Miscellaneous Diseases

One patient with lymphosarcoma showed no improvement and died after having received 8 7 g of R48 in 3 days

In a patient with giant follicular reticulosis wit generalised severe lymphadenopathy, treatment wit R48 for 32 days (total dose 6 4 g) did not affec the disease On the contrary, the pre existing gland increased somewhat and additional glands becam enlarged during the treatment Subsequently a cour of tris β chloroethylamine was given, with considerabl diminution in size of the lymph nodes

Finally, a case of mycosis fungoides treated with R4 is reported

Mrs A , aged 40, had noted a red patch on the left thigh f many years Since November, 1948, new red patches ha appeared on both lower extremities A further spread ha occurred in August, 1949, when similar lesions appeared o the forearms At the beginning of October, 1949, a vesic appeared in the original lesion of the left thigh, and soon a ulcer formed Skin biopsy confirmed the diagnosis of mycos fungoides Apart from the skin lesion the general conditic was very good On the internal surface of the left thig there was a tumour 5 cm in diameter, with a deep o oozing ulcer , the base of the ulcer was covered with necrot greyish substance In addition, there were about a doze patches (about $^{3}/_{4}$ in diam) located on both legs, both forearms, and the left breast The patches were red and we defined , few of them were infiltrated, and the skin over the was scaly After X ray irradiation the ulcer healed towar the end of December, 1949, but a month later a new ulc appeared on the same thigh with the same characteristi as the first ulceration This time the patient was given course of R48, starting on Jan 18, 1950, with a daily dose o 100 mg Two weeks later a definite improvement was alread noticeable , the base of the ulcer began to dry and in tw months, after 5 5 g of R48 had been given the ulcer wa completely healed The hæmatological picture remaine unaffected throughout the treatment (red cells about 4 500 00 per c mm , Hb 90–100%, and white cells 9000–13,000 pe c mm)

The beneficial effects of nitrogen mustard in som cases of mycosis fungoides have been described b Henstell et al (1947), Osborne et al (1947), Philpot et al (1947), and Craver (1948)

DISCUSSION

Despite the small number and diversity of cases treate with R48, certain facts seem suggestive in the comparison of R48 with nitrogen mustard by intravenou administration

(1) The effect of R48 has been inferior to that of intra venous nitrogen mustard In our experience, in over 80% of patients with chronic leukæmia or Hodgkin's diseas satisfactory remission follows the first course of nitrogen mustard injections The remission includes a return of th white cell count to normal, a rise in the hæmoglobin leve considerable regression or total disappearance of enlarge

---

*Further details of the cases treated are given in a table obtainable on request from THE LANCET Office 7 Adam Street Adelphi London W C 2 ment of spleen or lymph nodes, and return of feeling of well being Our experience with R48 has not been equally satisfactory Remissions, when obtained, have been, in most cases, only partial The white-cell count returned to normal, but spleen and node masses either remained completely unaffected or were only partially obliterated

Thus a discrepancy between the effect of the treatment on the white cells, on the one hand, and on enlarged spleen and lymph nodes, on the other, was observed in most cases, and we consider this discrepancy to be a serious drawback—first because the leucocytosis constitutes only one element of the disease, and secondly because a fall of the white cell count necessitates discontinuance of treatment for fear of a severe leucopenia, and one has to wait until the white cell count rises before another form of treatment, such as intravenous nitrogen mustard, is given

(2) Whereas treatment with intravenous β-chloro alkylamine induces remissions quickly (usually within 20–30 days), the time in which R48 induced remissions varied widely The lengths of time between the beginning of the course and the restoration of the white cell count to normal in cases of chronic leukæmia were

Case no	*Type of leukæmia*	*No of days*	*Total dose (g)*
1	Lymphatic	21	6 6
2	Lymphatic	60	18 0
3	Lymphatic	34	13·6
4	Lymphatic	50	9 0
5	Myeloid	100	40 0
6	Myeloid	50	12 4

In cases of Hodgkin's disease the times from the start of treatment to the optimal regression of enlarged masses were

Case no	*No of days*	*Total dose (g)*
7	150	45 0
8	60	24 0
9	50	50 0

This wide variation in the length of the courses constitutes another drawback of R48 treatment, because it necessitates a long stay in hospital or frequent visits to the outpatient clinics

In brief, therefore, our impression from the therapeutic trial of R48 has been disappointing in many respects, for it does not seem to replace satisfactorily treatment with β chloro alkylamines On the other hand, R48 is effective by mouth in some cases and may therefore be of value in cases where intravenous administration is technically difficult or impossible

SUMMARY

Twenty-five patients were treated with β naphthyl di-2 chloroethylamine (R48) by mouth

Of eight patients with chronic lymphatic leukæmia, two responded to the treatment satisfactorily, in two the results were poor, and three died soon after the first course of treatment Another patient is still in the first course

Of five patients with chronic myeloid leukæmia, two showed a satisfactory response, one did not respond at all, one died soon after the first course was completed, and one is still in the first course

Of seven patients with Hodgkin's disease four responded well to the treatment, one did not respond at all, and two died.

No response was obtained in a patient with lymphosarcoma and in a patient with giant follicular reticulosis, one patient with mycosis fungoides responded well.

The results as a whole have been inferior to those obtained with the β-chloro alkylamines intravenously

This work was done during the tenure of the Sybil Mary Pilkington Fellowship by one of us (C G) and as part of a special investigation for the Medical Research Council, from whom a research grant was received Our thanks are due to Prof A Haddow for the supply of R48

ACROSCLEROSIS is relatively rare, and there is much conflict of opinion about whether it is an independent clinical syndrome or not

Acrosclerosis, scleroderma, sclerœdema adultorum, and dermatomyositis have been grouped together as dermato scleroses, because hardening of the skin is common to all of them at some time during their course (O'Leary 1943) They have other features, such as (1) involvement of the body musculature (this occurs in acrosclerosis, scleroderma, and dermatomyositis, but not in sclerœdema adultorum), (2) a tendency for the cutaneous involvement to be self limited, the œdema subsiding and leaving various degrees of atrophy, (3) pigmentation, which may occasionally be marked, and (4) calcinosis, or deposition of calcium in the skin and muscles (this is common to all except sclerœdema adultorum)

Difficulty arises in establishing these four conditions as separate entities Scleroderma and dermatomyositis have been regarded as one and the same disease (Dowling 1940, Freudenthal 1940), and Sellei (1934) was much criticised for suggesting that acrosclerosis should be considered quite apart from scleroderma Sellei is supported by O'Leary and Waisman (1943), who tabulate the differences—especially in sex incidence, prodromal symptoms, sites of lesions, prognosis, and pathogenesis—between the two conditions

The cardinal feature of acrosclerosis is its invariable association with the Raynaud phenomenon, this is usually well established months or years before the skin lesions appear, but occasionally the vasomotor and cutaneous signs appear almost simultaneously O'Leary and Waisman (1943) suggest that sclerodactylia must be regarded as a potential complication of Raynaud's syndrome Raynaud himself noted the association of acral cutaneous sclerosis with the vasomotor symptoms which now bear his name

CLINICAL PICTURE

Changes in Skin

The cutaneous changes are essentially those of typical scleroderma, but they are confined to the distal parts of the extremities, the face, and the neck Over the fingers and hands the skin is thin, smooth, shiny, and tense The colour may be altered by pigmentary changes or by vascular disturbance, appearing coppery owing to increased pigmentation, or dusky or frankly cyanotic owing to impairment of circulation The fingers are characteristically rigid and held in a position of semiflexion and the skin over the dorsum of the hands is so adherent to the underlying structures that it is impossible to pick it up between the thumb and index finger These changes of the fingers and hands persist beyond the level of the wrists and merge into normal skin on the forearms Trophic changes—e g , ulcers—are commonly found on the backs of the fingers, and

patient developed a moderate dysuria with microscopical hæmaturia, but both conditions cleared completely as soon as treatment was stopped A generalised purpuric rash developed in another patient without thrombocytopenia, but cleared satisfactorily In two other cases a transient maculopapular rash was noted, but further treatment was given uneventfully In no case was there any relation between the appearance of toxic symptoms and the daily or total dose of the drug administered

RESULTS*

Acute Leukæmia

Two patients with acute leukæmia were treated with R48 One was given total doses of 6 8 g in 17 days, and the other 21 6 g in 30 days The disease followed its usual course without any symptomatic relief or objective improvement

Chronic Myeloid Leukæmia

Five cases of chronic myeloid leukæmia were treated In two cases satisfactory clinical and hæmatological remissions were obtained the white cell counts fell from 139,000 to 13,600 per c mm and from 233,000 to 16,000 per c mm , the hæmoglobin values rose moderately , the general condition improved , and the feeling of well being returned Splenomegaly regressed considerably in one patient but remained almost unaffected in the other Both patients have had repeated courses , both are alive and well with fairly good working capacity 20 and 22 months after the institution of the treatment In the third case there was no improvement, though the white cell count fell from 158,000 to 42,000 per c mm , the patient died 2 months after R48 treatment was started, but by then he had reached a very advanced stage, having received treatment previously with urethane and other agents for 30 months The fourth case was in a boy, aged 17 with 6 months' history of subjective symptoms and presenting a typical clinical and hæmatological picture of chronic myeloid leukæmia He had had no previous treatment and was given R48 300 mg daily for 30 days—a total dose of 9 g At the end of this period the lymph node and splenic enlargements remained the same, and the white cell count rose from 120,000 per c mm before treatment to 290,000 per c mm Subsequent treatment with intravenous tris β chloroethylamine produced very rapidly a good remission Another patient has had treatment for only a short time but is responding satisfactorily

Chronic Lymphatic Leukæmia

Eight cases of chronic lymphatic leukæmia were treated In two the results were satisfactory , good and long remissions were obtained, and both patients are well, with full working capacity, 22 and 20 months after the start of treatment with R48 Two other patients presented only remissions in their constitutional symptoms but no reduction of lymphadenopathy They have not yet returned to work 19 and 4 months since treatment with R48 was first given In three other patients, although the white cell counts returned to normal, the lymph node and splenic enlargements showed no changes, the anæmia did not improve, and the patients died 1, 1, and 9 months after treatment with R48 had been begun, without any apparent relief of the clinical course of the disease Another patient has had treatment for only a short time

Hodgkin's Disease

Seven patients have been treated In three the results were very good and the involved tissues regressed completely or almost completely The quantities required to produce these remissions were 5 g in 50 days, 45 g in 150 days, and 24 g in 60 days The general condition was good in all three cases and has remained good until now, 7, 20, and 24 months since treatment began Another patient was a woman of 45 who had previously been treated with intravenous tris β chloroethylamine for 2 years, which had produced such remarkably good results in this time that she had continued to run a very busy company and had regained her well being, she had gained so much weight as to render it very difficult to give intravenous therapy owing to poor access to veins, and so for over 12 months now she has been maintained on R48 with good response One patient has severe Hodgkin's disease involving soft tissues and skeletal structures, and has responded quite well to intravenous therapy Owing to technical difficulty with her veins also, she has been put on to R48 orally, but the response is not very good In two other cases the treatment failed and both patients died after having received 3 3 g in 24 days and 3 4 g in 17 days

Miscellaneous Diseases

One patient with lymphosarcoma showed no improvement and died after having received 8 7 g of R48 in 30 days

In a patient with giant follicular reticulosis with generalised severe lymphadenopathy, treatment with R48 for 32 days (total dose 6 4 g) did not affect the disease On the contrary, the pre existing glands increased somewhat and additional glands became enlarged during the treatment Subsequently a course of tris β chloroethylamine was given, with considerable diminution in size of the lymph nodes

Finally, a case of mycosis fungoides treated with R48 is reported

Mrs A , aged 40, had noted a red patch on the left thigh for many years Since November, 1948, new red patches had appeared on both lower extremities A further spread had occurred in August, 1949, when similar lesions appeared on the forearms At the beginning of October, 1949, a vesicle appeared in the original lesion of the left thigh, and soon an ulcer formed Skin biopsy confirmed the diagnosis of mycosis fungoides Apart from the skin lesion the general condition was very good On the internal surface of the left thigh there was a tumour 5 cm in diameter, with a deep oval oozing ulcer the base of the ulcer was covered with necrotic greyish substance In addition, there were about a dozen patches (about $^{3}/_{4}$ in diam) located on both legs, both forearms, and the left breast The patches were red and well defined , few of them were infiltrated, and the skin over them was scaly After X ray irradiation the ulcer healed towards the end of December, 1949, but a month later a new ulcer appeared on the same thigh with the same characteristics as the first ulceration This time the patient was given a course of R48, starting on Jan 18, 1950, with a daily dose of 100 mg Two weeks later a definite improvement was already noticeable , the base of the ulcer began to dry and in two months, after 5 5 g of R48 had been given, the ulcer was completely healed The hæmatological picture remained unaffected throughout the treatment (red cells about 4,500 000 per c mm , Hb 90–100%, and white cells 9000–13,000 per c mm)

The beneficial effects of nitrogen mustard in some cases of mycosis fungoides have been described by Henstell et al (1947), Osborne et al (1947), Philpott et al (1947), and Craver (1948)

DISCUSSION

Despite the small number and diversity of cases treated with R48, certain facts seem suggestive in the comparison of R48 with nitrogen mustard by intravenous administration

(1) The effect of R48 has been inferior to that of intravenous nitrogen mustard In our experience, in over 80% of patients with chronic leukæmia or Hodgkin's disease satisfactory remission follows the first course of nitrogen mustard injections The remission includes a return of the white cell count to normal, a rise in the hæmoglobin level, considerable regression or total disappearance of enlarge-

---

*Further details of the cases treated are given in a table obtainable on request from THE LANCET Office 7 Adam Street Adelphi London W C 2 ment of spleen or lymph nodes, and return of feeling of well being. Our experience with R48 has not been equally satisfactory. Remissions, when obtained, have been, in most cases, only partial. The white-cell count returned to normal, but spleen and node masses either remained completely unaffected or were only partially obliterated.

Thus a discrepancy between the effect of the treatment on the white cells, on the one hand, and on enlarged spleen and lymph nodes, on the other, was observed in most cases, and we consider this discrepancy to be a serious drawback—first because the leucocytosis constitutes only one element of the disease, and secondly because a fall of the white cell count necessitates discontinuance of treatment for fear of a severe leucopenia, and one has to wait until the white cell count rises before another form of treatment, such as intravenous nitrogen mustard, is given.

(2) Whereas treatment with intravenous β-chloro alkylamine induces remissions quickly (usually within 20–30 days) the time in which R48 induced remissions varied widely. The lengths of time between the beginning of the course and the restoration of the white-cell count to normal in cases of chronic leukæmia were:

Case no	*Type of leukæmia*	*No of days*	*Total dose (g)*
1	Lymphatic	21	6·6
2	Lymphatic	60	18·0
3	Lymphatic	34	13·6
4	Lymphatic	50	9·0
5	Myeloid	100	40·0
6	Myeloid	50	12·4

In cases of Hodgkin's disease the times from the start of treatment to the optimal regression of enlarged masses were:

Case no.	*No of days*	*Total dose (g)*
7	150	45·0
8	60	24·0
9	50	50·0

This wide variation in the length of the courses constitutes another drawback of R48 treatment, because it necessitates a long stay in hospital or frequent visits to the outpatient clinics.

In brief, therefore, our impression from the therapeutic trial of R48 has been disappointing in many respects, for it does not seem to replace satisfactorily treatment with β chloro alkylamines. On the other hand, R48 is effective by mouth in some cases and may therefore be of value in cases where intravenous administration is technically difficult or impossible.

SUMMARY

Twenty five patients were treated with β naphthyl di-2-chloroethylamine (R48) by mouth.

Of eight patients with chronic lymphatic leukæmia, two responded to the treatment satisfactorily, in two the results were poor, and three died soon after the first course of treatment. Another patient is still in the first course.

Of five patients with chronic myeloid leukæmia, two showed a satisfactory response, one did not respond at all, one died soon after the first course was completed, and one is still in the first course.

Of seven patients with Hodgkin's disease four responded well to the treatment, one did not respond at all, and two died.

No response was obtained in a patient with lymphosarcoma and in a patient with giant follicular reticulosis; one patient with mycosis fungoides responded well.

The results as a whole have been inferior to those obtained with the β-chloro-alkylamines intravenously.

This work was done during the tenure of the Sybil Mary Pilkington Fellowship by one of us (C. G.) and as part of a special investigation for the Medical Research Council, from whom a research grant was received. Our thanks are due to Prof. A. Haddow for the supply of R48.

M.D. Lpool, D.P.H.
PHYSICIAN TO THE DEPARTMENT OF DERMATOLOGY

BIRKENHEAD GENERAL HOSPITAL

ACROSCLEROSIS is relatively rare, and there is much conflict of opinion about whether it is an independent clinical syndrome or not.

Acrosclerosis, scleroderma, sclerœdema adultorum, and dermatomyositis have been grouped together as dermatoscleroses because hardening of the skin is common to all of them at some time during their course (O'Leary 1943). They have other features, such as (1) involvement of the body musculature (this occurs in acrosclerosis, scleroderma, and dermatomyositis, but not in sclerœdema adultorum); (2) a tendency for the cutaneous involvement to be self-limited, the œdema subsiding and leaving various degrees of atrophy; (3) pigmentation, which may occasionally be marked; and (4) calcinosis, or deposition of calcium in the skin and muscles (this is common to all except sclerœdema adultorum).

Difficulty arises in establishing these four conditions as separate entities. Scleroderma and dermatomyositis have been regarded as one and the same disease (Dowling 1940, Freudenthal 1940), and Sellei (1934) was much criticised for suggesting that acrosclerosis should be considered quite apart from scleroderma. Sellei is supported by O'Leary and Waisman (1943), who tabulate the differences—especially in sex incidence, prodromal symptoms, sites of lesions, prognosis, and pathogenesis—between the two conditions.

The cardinal feature of acrosclerosis is its invariable association with the Raynaud phenomenon; this is usually well established months or years before the skin lesions appear, but occasionally the vasomotor and cutaneous signs appear almost simultaneously. O'Leary and Waisman (1943) suggest that sclerodactylia must be regarded as a potential complication of Raynaud's syndrome. Raynaud himself noted the association of acral cutaneous sclerosis with the vasomotor symptoms which now bear his name.

CLINICAL PICTURE

Changes in Skin

The cutaneous changes are essentially those of typical scleroderma, but they are confined to the distal parts of the extremities, the face, and the neck. Over the fingers and hands the skin is thin, smooth, shiny, and tense. The colour may be altered by pigmentary changes or by vascular disturbance, appearing coppery owing to increased pigmentation, or dusky or frankly cyanotic owing to impairment of circulation. The fingers are characteristically rigid and held in a position of semiflexion, and the skin over the dorsum of the hands is so adherent to the underlying structures that it is impossible to pick it up between the thumb and index finger. These changes of the fingers and hands persist beyond the level of the wrists and merge into normal skin on the forearms. Trophic changes—e.g., ulcers—are commonly found on the backs of the fingers, and the hands are cold and often moist A similar condition, but usually less severe, is found on the lower extremities Here abnormal skin usually merges with normal skin below the knee, and deformity is not as apparent as it is in the hands, but clawing of the toes and complete immobility of the ankles may ensue The feet are cold, yet sweating

Calcium may be deposited in the soft tissues, when this true calcinosis coincides with sclerodermatous skin changes it constitutes the Thibierge Weissenbach syndrome (Lindsay et al 1943)

Facial sclerosis may coincide with the appearance of sclerodactylia, or its onset may be delayed for some years (Ormsby and Montgomery 1948) As the condition develops, the skin of the face becomes drawn and taut, and all its mobility is lost The lips are thinned and radially furrowed, and small furrows may appear on the chin The nose is prominent, sharp, and pinched, giving the patient a rather "peaked" expression, because the skin is stretched taut over the underlying cartilage The skin of the eyelids is involved, and the process also spreads down the neck to the clavicles, where it gradually merges with normal skin covering the thorax and shoulders In the fully established case the face may appear like that of a corpse (Ormsby and Montgomery 1948), with pigmentation of the facial skin and telangiectasis, the coppery hue suggesting Addison's disease Pruritus is uncommon, the first symptom of any skin change is stiffness In contrast to true scleroderma, acrosclerosis does not progress but remains confined to the face and extremities for many years, it may partly regress even after twenty years (O'Leary and Waisman 1943)

Histologically the skin resembles that seen in diffuse scleroderma (O'Leary 1943) The first published notes on the histology of this type of cutaneous lesion were those of Crocker (1880), who found the epidermis unaltered except for pigmentation and the occasional presence of a few wandering leucocytes, the corium with papillæ less prominent than usual and with perivascular lymphocytic infiltrations, and the ducts of the glands obliterated by fibrous tissue Modern histopathologists have elaborated further, and attention is now focused on the collagen tissues of the body (O'Leary and Waisman 1943, Ormsby and Montgomery 1948, Klemperer et al 1942, O'Leary and Nomland 1930, Lewis 1940, Freudenthal 1940) The first sign is an œdema of the collagen bundles in the cutis, which causes swelling and separation of the bundles As the process continues, its sclerosing nature is made manifest, the bundles losing their fine fibrillary structure and becoming hyalinised and matted together Changes in the elastic tissue are variable, some workers recording absence of, or diminution in the number of, elastic fibres, whereas others find these normal or possibly thickened The vessels may show "cuffing" with mononuclear cells, chiefly lymphocytes, and plasma cells, and obliterative sclerosing changes chiefly involving the intima The epidermal changes are not well marked and are only secondary to the œdema and sclerosis of the underlying tissue The epidermis is thinned, and the rete pegs are flattened and fewer than normal (Freudenthal 1940) Subcutaneous fat is absent, and there is atrophy of the dermal appendages, the sweat glands being probably least affected (Ormsby and Montgomery 1948) Increased melanin pigmentation may be seen

Arthralgia

As well as the more obvious cutaneous manifestations, arthralgia and dysphagia may accompany acrosclerosis The arthralgia may, as with the Raynaud phenomena, be a premonitory symptom, but Sellei (1934) refers to changes in the joints, in addition to the flexion of the phalanges, which he terms pseudo arthritis deformans

Dysphagia

The dysphagia is of several kinds (1) difficulty in initiating deglutition, owing to the rigidity of the face, (2) difficulty in opening the mouth and in mastication, and (3) true dysphagia, which is present in over 10% of the patients (Ormsby and Montgomery 1948) A retrosternal burning sensation may be the first symptom of œsophageal involvement Involvement of the œsophagus can be detected by radioscopy or by endoscopy, including biopsy

The œsophageal changes are apparently identical with those of scleroderma and have been well described by Olsen et al (1945) Dysphagia in scleroderma was first recorded by Ehrmann (1903), who did an œsophagoscopy and noted changes in the œsophageal mucosa Schmidt (1916) reported on the radiological appearances after a barium swallow in a patient who had scleroderma with dysphagia although no lesion was detected in the œsophagus, fifteen minutes was required to allow for passage of the barium into the stomach, and the greatest delay was noticed at the cardia, where peristalsis was less than normal In 15 of 18 cases of acrosclerosis reported by Olsen et al (1945) conclusive radiological findings were demonstrable œsophageal dilatation with atony of the œsophageal musculature was noted in 6 (*peristalsis was decreased or absent in these*), apparent spasm at the cardia, with obstruction, was noted in 4, and the passage of barium was slower than normal The radiological diagnosis in all these cases was one of cardiospasm This finding supports the clinical manifestations, the patients often localising their symptoms to the lower end of the œsophagus Olsen et al (1945) observe that œsophageal lesions tend to occur in advanced cases of acrosclerosis, and therefore the prognosis is not good, and they correlate Raynaud phenomena and cardiospasm as being due to disturbance of the autonomic nervous system They suggest that some common ætiological factor exists in the vasomotor, dermatological, and œsophageal disturbances observed in acrosclerosis. The œsophageal dysfunction can be traced from simple delay in the passage of barium to stricture formation in the lower part of the œsophagus Histologically the picture is one of sclerosis of the connective tissues The submucosa is infiltrated with round cells, and there is well marked perivascular infiltration, with fragmentation of the elastic fibres and atrophy of the muscularis Finally, Olsen et al (1945) comment that œsophageal disturbances are extremely rare in patients exhibiting the Raynaud syndrome alone Lindsay et al (1943) have described œsophageal changes in scleroderma resembling those described by Olsen et al (1945) in acrosclerosis

Changes in Muscle

These are well known in scleroderma but are regarded as inconstant in acrosclerosis (O'Leary 1943) O'Leary and Waisman (1943) described interstitial inflammation and homogenisation of muscle bundles The histological picture in cases which show muscle involvement is similar to that found in generalised scleroderma, and has been fully described by Freudenthal (1940), it includes œdema, hyalinisation of fibres, abnormal staining reactions, and loss or blurring of cross striations The nuclei are often increased in number and are characteristically arranged in longitudinal rows along the sarcolemma (Freudenthal 1940) Infiltration is variable, when it occurs the cells are mononuclears—usually lymphocytes—with occasional plasma cells Occasionally the lymphocytes aggregate together, and these little colonies are called "lymphorrhages" These lesions were first described by Weigert (1901) in myasthenia gravis. Buzzard (1905) suggested the term "lymphorrhage" because the lymphocytic aggregations resemble capillary diapedesis of red blood cells Dudgeon and Urquhart (1926) have described these lymphocytic infiltrations in scleroderma Since germ centres are present, these "lymphorrhages" are thought by some workers to represent aberrant lymphatic tissue because of their high degree of differentiation

Changes in Lungs

Very rarely there are cystic changes in the lungs in scleroderma and acrosclerosis These cysts vary in size and may be found towards the periphery of the lung, away from the hilum , they are multiple, close together, and supported by narrow septa These changes are summarised by Dostrovsky (1947) as a sclerotic change in the lungs, followed by dissolution of the alveoli, with cyst formation

CASE RECORD

A childless married woman, aged 46, was first seen in January, 1947, with about a year's history of typical Raynaud phenomena Before this she had always enjoyed good health There was nothing relevant in her family history The Raynaud attacks were aggravated by exposure to cold, but they also occurred spontaneously, and during an attack the finger tips of both hands became cyanosed and numb The cyanosis began as a light bluish tint, later became a deeper blue, and gradually spread proximally towards the base of the fingers The condition subsided after a few minutes, and the colour of the skin became normal About a year after the onset of the Raynaud attacks the patient had noticed the onset of stiffness in the fingers and hands There had been no arthralgia, but the patient had speedily become incapable of moving her fingers or wrists Within a month the skin of her face, neck, and hands had become coppery and, as this pigmentation had subsided, all these areas had become sclerotic Lastly the feet had become affected, but never to the same extent as the other parts

On admission in February, 1947, the skin over the wrists, hands, and fingers was thin smooth, shiny, and tense The fingers and wrists were rigid, the fingers being held in a position of semi flexion and there was slight ulnar deviation at the wrists It was impossible to pinch up a fold of skin between the finger and thumb, and the affected skin traced up the arm, gradually merged into normal skin in the region of the elbows Frequent Raynaud phenomena were noted The facies was typical of the condition The skin was ivolved to a level just covering the shoulders and beneath oth clavicles, and then it merged almost imperceptibly ith more normal skin Similar, but less severe, changes ere present in both lower extremities and limited movement as present at both ankle joints Increased pigmentation f patchy distribution on the neck and on the dorsum of rists and hands was noted The blood pressure was 108/65 m Hg but no gross abnormality was detected in the espiratory, alimentary, or central nervous systems

Investigations —A blood count and the erythrocyte edimentation rate (E S.R) were normal The blood uric acid evel was 2 mg per 100 ml and blood calcium level 10 5 mg er 100 ml Radiography revealed no evidence of pulmonary isease, and there were no visible cervical ribs Radiograms f the hands showed sclerosis of the tips of the terminal halanges thought to be due to impaired blood supply

Treatment —In view of the Raynaud phenomena, sympa hectomy was considered, and the patient was seen in con ultation with Mr J Bagot Oldham, who reported I am ery doubtful about the advisability of sympathectomy here, ecause sclerodactyly is well marked, and this condition is ot benefited by sympathectomy I might try the effect f a paravertebral block but, unless its result is very striking, I am opposed to any operation In view of these findings, the patient was discharged from hospital the treatment advised being physiotherapy, and thyroid extract by mouth This treatment was continued for some months without any material benefit to the patient, and she subsequently discontinued her attendance at the hospital and was not seen again until November 1948

On examination in November, 1948, there was no significant change in her condition, but she had become very distressed owing to her inability to perform any useful tasks

Readmission —She was readmitted in March 1949, the physical signs being the same as on her previous examination A new feature, not noted on her previous admission was the appearance of scars due to ulceration of the skin on the fingers Apart from these trophic changes the fingers were cylindrical and tapering at their tips, and were still held rigidly in a position of semi flexion, the extremities being cold and sweating

Investigations —A Wassermann reaction was negative A blood count showed slight hypochromic anæmia but no other abnormality The blood calcium level was 8 6 mg per 100 ml serum potassium 18 5 mg per 100 ml , serum sodium 294 mg per 100 ml , and blood urea 22 mg per 100 ml The Kepler factor was 33, suggesting that the patient had not got Addison's disease Plasma protein levels, albumin globulin ratio, E S R , and urine were normal A fractional test-meal showed hypochlorhydria Electrocardiography was normal Radiography of the chest showed no evidence of pulmonary disease, no cystic changes, and a normal cardiac outline After a barium swallow there was delay in passage of the barium through the œsophagus, but contractions were visible at all levels Radiography of the soft tissues showed no evidence of calcinosis, and of the wrists showed decalcification of bones only

Biopsy —Skin showed atrophy of the epithelium, with flattening and diminution in number of the rete pegs (papillæ) Some of the small blood vessels in the corium showed scanty perivascular lymphocytic infiltration Subcutaneous fat was practically absent, and the glands were compressed by sclerosis of the fibrous connective tissue Muscle showed non specific changes only

Treatment —The patient's repeated requests for treatment presented a difficult problem On rather empirical grounds, but supported by the low serum calcium levels, she was given calciferol 100,000 units daily, together with physio therapy, including inunction with bland oils One treatment with thorium X was given to the fingers This caused slight reddening of the skin, but neither the calciferol (which subsequently raised the serum calcium level to 9 8 mg per 100 ml) nor the thorium X produced any recognisable improvement

DIFFERENTIAL DIAGNOSIS

The earliest manifestations of acrosclerosis are the Raynaud phenomena, and until the skin changes appear the diagnosis of acrosclerosis does not arise Superficial examination may lead to a momentary confusion with rheumatoid arthritis Raynaud phenomena are seen in both conditions, and the ulnar deviation and position of flexion of the fingers are common to both Closer examination confirms, however, that the changes are not primarily articular or periarticular, and any deformities that have arisen are due to the contraction of the skin over the underlying tissues. In this way an entire limb may shrink in volume

Finally, acrosclerosis should be differentiated from diffuse progressive scleroderma (O'Leary and Waisman 1943) and poikilodermatomyositis (Bamber 1936) The salient points of difference between these four diseases are as follows

Acrosclerosis

(1) Occurs predominantly in females never attacks children
(2) Is always confined to the extremities and face and characterised by slow course and tendency to regress
(3) Vasomotor phenomena are a prominent accompanying feature
(4) Trophic changes in distal phalanges and ulceration of skin are common
(5) Much muscle wasting and weakness uncommon

Diffuse progressive scleroderma

(1) Occurs equally in both sexes may occur in children
(2) Often starts on the trunk and the whole body may be affected within three years
(3) Vasomotor phenomena insignificant
(4) Trophic changes inconstant
(5) Much muscle wasting and weakness may occur

Poikilodermatomyositis

(1) Occurs in both sexes may occur in children
(2) Whole body may be affected may run a rapid course
(3) Vasomotor phenomena especially in early stages of the disease inconstant
(4) Trophic changes in distal phalanges uncommon
(5) Much weakness and muscle wasting are a feature of the disease

Rheumatoid arthritis

(1) Predominates in females may occur in children
(2) Affects the joints rather than the skin but can produce total immobilisation within three years
(3) Vasomotor phenomena inconstant.
(4) Trophic changes uncommon
(5) Weakness and muscle wasting are common

ÆTIOLOGY

Autonomic Nervous System

The vasomotor phenomena, together with the œsophageal dysfunction, have led many workers to discuss the autonomic nervous system as a factor in the cause of acrosclerosis (O'Leary and Waisman 1943, Olsen et al 1945, Castle 1923, Leriche et al 1937, Sequeira 1916, Robinson 1917) In support of this hypothesis is the occurrence of tachycardia, sweating, and trophic changes Collier and Wilson (1913) found that the cells of the intermediolateral tract were undergoing degeneration, and it is from these cells that the sympathetic fibres arise Knapp (1911) reports lesions in the anterior horn of the spinal cord, and Howell (1914) points out that the distribution of the lesions tends to be segmental, the bilateral symmetry of the lesions is particularly noticeable in acrosclerosis

Endocrine System

Dysfunction of the ductless glands has long been associated with sclerodermatous changes in the integument "Lymphorrhages" and atrophy of muscle fibres are found in thyrotoxicosis and myasthenia gravis Circumscribed scleroderma has been associated with both exophthalmic goitre and myxœdema (Sequeira 1916) The thyroid gland varies enormously in different cases, but thryoid atrophy appears more common than hypertrophy Cases are on record in which Addison's disease and acromegaly have occurred in patients also presenting sclerodermatous skin lesions Osler (1898) found treatment with thyroid extract in no way specific and giving no real benefit to the patient Trauma, mental shock, and infectious disease have all been incriminated as the cause of sclerodermatous skin changes The parathyroid glands have also been under suspicion (Cornbleet and Struck 1937), and Selye (1932) has produced scleroderma like lesions in young rats by injecting parathyroid extract In man calcium is apparently mobilised from the bones and deposited in the soft tissues, and hypocalcæmia may ensue

A widespread endarteritis has been held to be responsible for the skin lesions, emphasis being laid on the changes in the digital arteries in the accompanying Raynaud syndrome It should be recalled, however, that œsophageal disturbances and scleroderma like skin lesions are never found in a pure Raynaud syndrome, the skin over the fingers may ulcerate and be ischæmic, but the changes of acrosclerosis are not seen

Castle (1923) considered that the essential underlying cause was a combination of a disordered function of the internal secretory glands and an affection of the nervous system He felt that the balance between the different members of the endocrine system was so delicate that, if any particular gland failed, the remainder acted so as to minimise that failure He was therefore of the opinion that it was impossible to fix the responsibility for scleroderma and acrosclerosis on any one gland

We are of the opinion that, of the ductless glands, the suprarenal is the one that falls chiefly under suspicion Hyperpigmentation is an almost constant accompaniment of acrosclerosis and scleroderma Winfield (1904) recorded two cases which rapidly improved after the administration of desiccated adrenal gland Barlow (1939) reported a case of scleroderma associated with adrenal neoplasm

There is an important interrelation between the sympathetic nervous system and the ductless glands The connecting link is the chromaffin tissue, which is widely distributed in the medulla of the suprarenals, sympathetic ganglia and plexuses, ovaries, &c This chromaffin system is intimately related to the sympathetic system in embryological derivation and location (Foerster 1916) The medulla represents about 10% of the total volume of each suprarenal gland, and is derived, in common with the ganglia of the sympathetic, from the neural tube in early embryonic life It is thus epiblastic in origin, and is intimately related to the sympathetic nervous structures (McEwen 1916) The cortex, which forms 90% of the volume of each suprarenal gland, is mesoblastic, springing from the genital ridge and therefore having a common origin with the sex glands When one considers the considerable vasomotor instability in cases of hyperthyroidism, the frequent onset of acrosclerosis and scleroderma in females approaching the menopause, and the fact that menstruation may be arrested coincidentally with the appearance of such skin lesions, one can appreciate why Castle (1923) put forward the belief that it is difficult to pin the responsibility for this disease on any single ductless gland

The suprarenal glands are well known to be concerned with the metabolism of salt and water, and it is worth while recalling that the earliest histological feature of acrosclerosis is œdema, swelling up and separating the collagen bundles and fibrils Again, clinically, the skin changes of scleroderma are often preceded by œdema, which, as it subsides, heralds the onset of the characteristic "hide bound" skin Further, the suprarenals are linked closely with the sex glands, cessation of menstruation and other sexual changes occur in suprarenal virilism The connecting link between the suprarenals and the sympathetic nervous system is their common origin from the neural tube in early embryonic life

We are therefore of the opinion that dysfunction of the suprarenal glands is the chief ætiological factor in the pathogenesis of acrosclerosis The autonomic imbalance, hyperpigmentation, œdema, sex incidence, and associated sexual disturbances—e g, menstrual—can be explained fairly satisfactorily on this hypothesis, which links up with the ideas of earlier workers that the autonomic nervous system and the ductless glands are in some way responsible for the pathology of acrosclerosis.

TREATMENT

There is no satisfactory treatment for acrosclerosis. As noted above, acrosclerosis may partly regress, even after many years On general principles most workers recommend residence in a dry and equable climate, and a well balanced nutritious diet Protection of the fingers from trauma, including immersion in cold water, and the avoidance of psychological trauma are also advised. Physiotherapy is important, radiant heat and massage, together with active and passive movements, encourage the patient and should be tried in all cases

Surgical Treatment

This has been described by Leriche et al (1937), who have published their results with both sympathectomy and parathyroidectomy Their treatment by sympathectomy follows work done by Brown and O'Leary (1930), who studied microscopically the capillaries in the nail beds in acrosclerosis These workers concluded that there is a significant sympathetic hypertonia of the vessels in acrosclerosis Of 13 cases described by Leriche et al (1937), 5 were much improved and 4 somewhat improved They make it clear that the greatest improvement is to be expected in cases with antecedent Raynaud attacks and in which this phenomenon is a dominant feature

Because certain patients with acrosclerosis have hypercalcæmia, the same workers tried the effect of parathyroidectomy in selected cases. Selye (1932) has shown that the injection of young rats with parathyroid hormone produces a thickening of the skin similar to scleroderma Osteoporosis, calcinosis, hypotonia, and asthenia are said to be due to the hypercalcæmia in acrosclerosis Of another 13 patients subjected to para thyroidectomy 5 showed much improvement and 7 moderate improvement

Opotherapy

Thyroid extract (Robinson 1917), pituitary (Oliver and Lerman 1936), and suprarenal extracts have also been widely used in the treatment of acrosclerosis

Thyroid extract has long been used, although many workers, including Osler (1898) and Sequeira (1916), have been unable to benefit their patients by this means Since both hyperthyroidism and myxœdema have been recorded coincidentally with sclerodermatous skin lesions, it is difficult to postulate the effect of thyroid extract on the course of acrosclerosis

Winfield (1904) described much improvement in a single case given suprarenal extract, and Schwartz (1917) treated 6 cases with pituitary extract and reported improvement in all

Miscellaneous

Gold, anti histamine drugs—e g, 'Benadryl'—neostigmine methyl sulphate, T A B vaccine, thorium X, and calciferol have all been advocated but are only palliative Dysphagia due to œsophageal involvement may be relieved by the passage of sounds

SUMMARY

Acrosclerosis is defined, and its characteristic features are outlined

The literature is reviewed, and a further case reported

The ætiology is discussed, with special reference to the suprarenal glands It is suggested that these glands may ultimately be directly concerned in the pathogenesis of acrosclerosis

Treatment, both medical and surgical, is briefly surveyed

We wish to thank Dr Leslie Cunningham, senior physician to the Birkenhead General Hospital, for permission to publish this case

EFFECT OF IMPLANTATION OF TABLETS OF INSULIN ON NORMAL AND ALLOXAN-DIABETIC RABBITS

I C GILLILAND
M D Edin, M R C P,
MEDICAL TUTOR AND SENIOR MEDICAL REGISTRAR

M MENCER MARTIN
M B Durh M R C P
FORMERLY LUND RESEARCH FELLOW, DIABETIC ASSOCIATION RESEARCH REGISTRAR DIABETIC DEPARTMENT, KING'S COLLEGE HOSPITAL

From the Postgraduate Medical School of London

THE present practice of giving insulin by injection has many obvious disadvantages, and alternate routes of administration have been repeatedly investigated The introduction of long acting protamine insulin by Hagedorn et al (1936) has helped to achieve a better control in many diabetic patients, without, however, solving the problem of the daily injections Oral, intra nasal, rectal, and vaginal routes, as well as subcutaneous implantation of pellets, have all been tried from time to time but have been abandoned because the insulin effect was either absent or inconstant and unreliable However, Vargas (1949) claims that tablets or pellets of protamine zinc insulin (P Z I), either alone or mixed with equal quantities of cholesterol, act for a long time when implanted subcutaneously

We report here experiments made to test the effectiveness of subcutaneous implants of pellets prepared according to the directions of Vargas (1949) and of two other similar types of pellets, prepared from P Z I and neutral P Z I (Kirkpatrick 1949) The criteria of activity were the effects on the blood sugar level of normal and alloxan diabetic rabbits and on the glycosuria of the diabetic rabbits

METHOD

Animals

Rabbits[*] were rendered diabetic (Duffy 1945) by giving them alloxan 200 mg per kg of body weight in a 4% solution intravenously, the solution being neutralised with sodium hydroxide immediately before use A 5% glucose drink was offered for the subsequent two days and given by stomach tube if hypoglycæmic symptoms were noted The subsequent progress of the rabbits was studied by estimation of body weight, blood sugar level, urinary excretion of sugar, and amount of urine excreted per twenty four hours After four days 2 5–7 5 units of P Z I was injected to prevent acidosis maintain nutrition, and keep the urinary loss of sugar at less than 10 g per day At intervals this insulin was omitted to assess the severity of the diabetes Both the extent of the uncontrolled glycosuria and the insulin requirements remained fairly stable from three weeks after the administration of alloxan

Preparation of Tablets

(1) Tablets of equal quantities of P.Z I and cholesterol estimated to contain 500 and 1000 units of P.Z.I were prepared for us under aseptic conditions by Burroughs Wellcome & Co according to the directions of Vargas (1949)

(2) Two tablets of P Z.I mixed with calcium carbonate were made by us in a hand tableting machine lent by Burroughs Wellcome & Co The P Z I powder was obtained by centrifuging commercial P.Z.I, passing the product through alcohol and acetone, and drying it in a vacuum desiccator over phosphorus pentoxide 20 mg of powder, the whole from a solution of 400 unit strength, was used for each tablet, mixed with 100 mg of calcium carbonate

(3) Tablets of neutral P.Z I estimated to contain 500 and 1000 units of insulin and tablets of equal quantities of neutral P.Z I. and cholesterol estimated to contain 1000 units of insulin each were prepared for us by Messrs Boots Pure Drug Co

---

[*] Male rabbits weighing 2000–3000 g were used in all the experiments and kept in metabolic cages They were fed on a standard diet of oats 60 g and bran 60 g moistened with water 200 ml green cabbage-leaves 60 g and carrots 100 g daily They were allowed water ad lib Rejected food was removed and measured at 6 P M each evening Fasting blood sugar levels were obtained before feeding at 10 A.M The fasting blood sugar levels of normal rabbits under these conditions were 91 7–S.D 18 7 mg per 100 ml (range 56–127 mg per 100 ml in 36 observations)

TABLE I—EFFECT OF P Z I -CHOLESTEROL IMPLANTS ON FASTING BLOOD SUGAR OF NORMAL RABBITS

Insulin given	None	P Z I and cholesterol implanted	Daily injections of P Z I (2 0–4 2 units)	None	P.Z.I and cholesterol implanted
Fasting blood sugar (mg per 100 ml) (mean S D or range)	91 7 ± 18 7	87 5 ± 18 8	43 7	74 8 (56–97)	72 9 (50–100)
No of rabbits	30	9	3	3	5
No of observations	56	55	5	5	10
Duration of fast	12 hours			40 hours	

Implantation

A small area on the flank of the rabbit was shaved, and an incision was made about 0 5 cm long With sinus forceps the space between the skin and subcutaneous tissue was opened, and a tablet was dropped in In a similar way implantation into the abdominal wall was carried out, and on two occasions into the peritoneal cavity and into muscle The wound was closed with a single stitch This process had remarkably little disturbing effect on the rabbits

TABLE II—FASTING BLOOD SUGAR LEVELS OF 3 DIABETIC RABBITS IN 3 CONSECUTIVE 5 DAY PERIODS

—	First period	Second period	Third period
Insulin given	None	P Z.I and cholesterol implanted	Implant plus daily injection of P Z I (2 units)
Fasting blood sugar (mg per 100 ml) (mean S D)	367 ± 52 3*	364 ± 56 5	197 ± 77 4
No of observations	15	13	25

* Mean fasting blood sugar of another 15 diabetic rabbits—342 ± 62 2 mg per 100 ml (93 observations)

Estimations

Blood sugar levels were estimated according to the Harding modification of the Schaffer Hartman method (King 1947) on 0 1 ml of blood from the rabbit s ear vein Urinary sugar was estimated by the Meyer modification of Benedict s method (King 1947) on twenty four hour samples of urine

RESULTS

P Z I Cholesterol Tablets

Nine *normal rabbits* (table I) were implanted with tablets of 500–2500 units Further implants of 500 and 1000 units were given to two of these rabbits, and the rabbit which had been given 2500 units was given 10,000 further units after ten days' observation from the initial implant Neither in these rabbits nor in controls was any fall in fasting blood sugar noted over periods of thirty to a hundred days By contrast, daily injection of P Z I solution of 2–4 2 units of P Z I per kg of body weight about halved the fasting blood sugar

Tablets of 500, 1000, and 1500 units were implanted in three *diabetic rabbits* (table II) thirteen days after withdrawal of their maintaining daily insulin injections of 2 5–5 0 units The 1000 and 1500 unit tablets should, according to Vargas, provide absorption equivalent to more than any of the maintaining doses After five days without apparent response daily injections were resumed, and an immediate effect was observed on the glycosuria and fasting blood sugar levels (fig 1)

Of the 26 tablets used, 21 were recovered apparently intact three months after implantation Their weight was found comparable with that of unimplanted tablets (table III) An acid saline extract of one of these tablets crushed lowered the rabbit's blood sugar dramatically However, no insulin effect was demonstrable after implanting a crushed tablet, or after subcutaneous injection of a sterile water extract from a crushed tablet Burroughs Wellcome & Co assayed other tablets of the same batch and reported that three months after manufacture they still contained at least 80% of their stated insulin content They made an acid saline extract of the tablets and assayed its effectiveness by their standard mouse convulsive procedure with comparison with a known dose of insulin

P Z I and Calcium Carbonate Tablets

Observations were made with two of these tablets estimated to contain 400 units of P Z I, and a control tablet of calcium carbonate of equal weight in three diabetic rabbits Implantation was made after twelve hours' fast, which was continued for a further seven hours The standard régime was then resumed. The blood sugar levels observed are shown in fig 2 A fall is shown maintained for about four days

Tablets of Neutral P Z I

Six normal rabbits were implanted subcutaneously in the dorsal region with tablets of neutral P Z I Three rabbits were implanted with 500 units, and three with 1000 units each They were made to fast for seven hours, by which time the blood sugar level of all of them had fallen below 30 mg per 100 ml One rabbit was lost at this point, but five recovered after being fed After forty eight hours the morning blood sugar levels had returned to within normal limits

Three normal rabbits were implanted with 1000 unit tablets, one intraperitoneally, one into the abdominal wall, and one intramuscularly into the thigh Their blood sugar levels fell to below 30 mg in seven hours. The

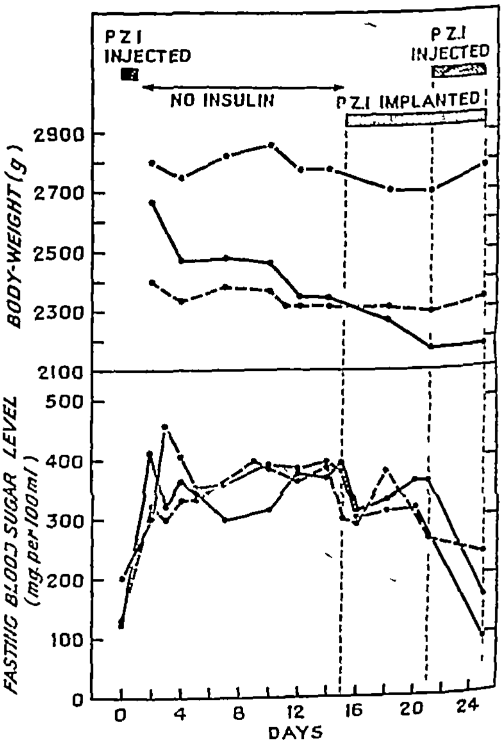

Fig 1—Weights and fasting blood-sugar levels of three diabetic rabbits on insulin, off insulin and after implantation of P Z I.-cholesterol tablets

rabbits were then fed The one which had had the tablet implanted into the abdominal wall died in hypoglycæmia The other two survived, and their blood sugar levels returned to normal in forty eight hours

Seven diabetic rabbits were implanted—three with 500 units each, and four with 1000 units each There was a pronounced effect on the blood sugar levels, which dropped to 70–130 mg per 100 ml within twenty four hours, with a corresponding improvement in the glycosuria After forty eight hours this effect was no longer apparent

All the tablets were removed ten days after implantation, but owing to their friable state only 3 were removed intact These showed on weighing an average loss of 4 6 mg , equivalent to a loss of 90 units of insulin

Histological examination of the site from which the tablets were removed confirmed the impression that these tablets had been " encapsulated " A considerable foreign body cell reaction was found round the tablets (fig 3)

One tablet was reimplanted into the same rabbit from which it had been removed, and it again showed a well marked insulin effect lasting for forty eight hours as before Saline extracts made from other removed tablets were also found to cause hypoglycæmia

Tablets of Neutral P Z I and Cholesterol

Three diabetic rabbits were implanted with one tablet each of the mixture of neutral P Z I and cholesterol estimated to contain 1000 units of insulin After implantation the rabbits were made to fast for seven hours, by which time the blood sugar levels of all three had fallen to below 80 mg per 100 ml The rabbits were then fed on the standard diet Within two days the fasting blood sugar levels were back to the original diabetic levels

TABLE III—WEIGHT OF IMPLANTS OF P.Z.I. AND CHOLESTEROL 2 MONTHS AFTER IMPLANTATION

Tablet size	Mean initial weight of 14 implanted tablets (mg)	Mean weight of tablets 3 months after implantation (mg)	
500 unit	91	83·3	(7)*
1000 unit	182	182·6	(14)*

* No of tablets

Two further implants of 1000 units each were given to these rabbits at weekly intervals with similar transient effects

After one to three weeks' implantation the tablets were removed and they were found to be 3–15 mg heavier than when implanted

Histological examination of the tablets removed showed encapsulation by a foreign-body reaction similar to that observed round the tablet of neutral P Z.I mentioned above

DISCUSSION

Parkes and Young (1939) experimented with rabbits, using 5 mg pellets of crystalline or low-zinc insulin containing 100 units each and found that they were absorbed within twenty four hours Mark and Biskind (1940) showed that pellets of crystalline zinc insulin with protamine effectively lowered the blood sugar of depancreatised dogs for as long as a hundred hours Their tablets, however, produced local reactions and they found a great variation in the rate of absorption of insulin from the tablets They found that the dried powder from commercial P Z I was ineffective Cutting et al (1941), also working with depancreatised dogs, found that pellets of zinc insulin with cholesterol, and pellets of zinc insulin with cholesterol and lecithin gave up their insulin slowly for as long as thirteen days

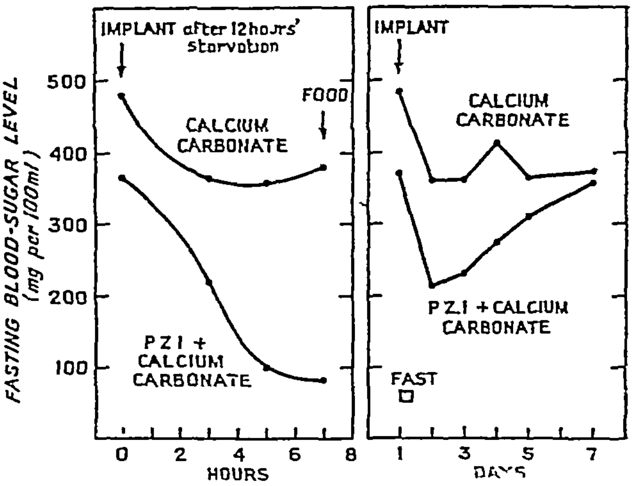

Fig 2—Fasting blood-sugar levels in diabetic rabbits after implantation of P Z.I and calcium carbonate and after implantation of calcium carbonate alone.

The irregularities of absorption, however, were too great, in their opinion, to justify clinical trials of such pellets Further experiments along the above lines were carried out by Parkes (1942) and McCullagh and Lewis (1942) confirming the above results and the fact that subcutaneous implants of insulin seemed too unreliable for clinical use

Vargas and Koref (1949) claimed that tablets or pellets of P Z I , either alone or mixed with an equal quantity of cholesterol were absorbed so slowly as to produce an insulin effect on the blood sugar levels of normal rabbits for as long as fifty days In alloxan diabetic rabbits the diabetic and associated metabolic changes were said to have been controlled for about a hundred days The same technique was then claimed to have been applied with success to human diabetes (Vargas 1949)

Such an important claim, even though it seemed to lack supporting data, nevertheless warranted testing We implanted tablets prepared according to the directions of Vargas (1949), but found no evidence of absorption, although the amounts implanted were in some cases considerably greater than those implanted by Vargas Our preliminary results with tablets of commercial P.Z.I alone were not very encouraging, for though the effect lasted for several days it was entirely out of proportion to the great number of units of insulin used Neutral P Z I was next tried in view of its stability and its better solubility at the pH of the body, but we could only show evidence of adequate absorption up

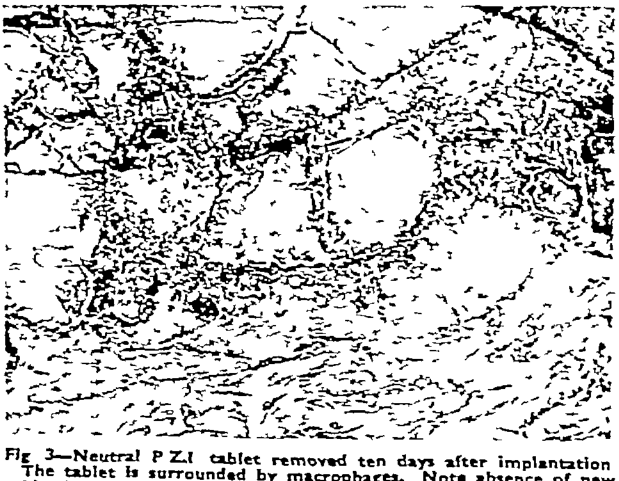

Fig 3—Neutral P Z.I tablet removed ten days after implantation The tablet is surrounded by macrophages. Note absence of new blood-vessels in surrounding tissues.

to two days Since we found insulin in the removed tablets and histological evidence that the tablets had been encapsulated, the problem clearly is to find a sufficiently insoluble insulin which will not be treated as a foreign body We were not able to do this

SUMMARY

Observations have been made of the effect of four types of insulin tablets implanted subcutaneously in 39 normal and 25 alloxan diabetic rabbits tablets of P Z I and cholesterol prepared according to the method of Vargas (1949), tablets of commercial P Z I powder mixed with calcium carbonate tablets of neutral P Z I , and tablets of neutral P Z I mixed with an equal quantity of cholesterol

No metabolic effects were noted from the P Z I and cholesterol tablets, whose weight three months after implantation had not altered Vargas's (1949) claim was thus not substantiated

After the implantation of P Z I tablets containing 400 units some insulin action was noted, lasting up to four days, but less than that obtained from the daily injection of 2 5 units of P Z I

An insulin action was noted from implanted tablets of neutral P Z I either alone or mixed with an equal quantity of cholesterol, but lasting only for about 2 days

Histological examination of the removed tablets showed encapsulation by a tissue reaction, which was evidently the reason for the short duration of their effects

We wish to thank Dr Russell Fraser for his help and advice, and Miss Shirley Looker, B SC , for her assistance with the biochemical estimations We are also indebted to the Diabetic Association for the grant of a Lund Research Fellowship to one of us (M M M) to do this work

LIVER FLUKE REMOVED FROM THE HUMAN COMMON BILE-DUCT

J S RAMAGE
M B Glasg , F R C S E
SURGEON, ROYAL INFIRMARY, STOKE ON TRENT

HUMAN infection with *Fasciola hepatica* is relatively rare The present case seems to be the second recorded instance of removal of a liver fluke from the common bile duct at operation * Manson Bahr and Walton (1941) reported the first case

A farmer's wife, aged 64, who lived in the country between Leek and Buxton, began in 1947 to have attacks of pain in the right upper abdomen Her doctor diagnosed subacute cholecystitis Between these attacks she was jaundiced on three occasions without much abdominal discomfort

Cholecystography revealed a large number of gall stones in the gall bladder A blood count showed no abnormality Eosinophilia was 1%

At *operation* in September, 1949, the gall bladder was found to be packed with stones the largest being about 1 in in diameter Cholecystectomy was performed The common duct appeared somewhat dilated, though palpation of it revealed no stones In view of the numerous attacks of jaundice, however, the common duct was incised to make certain that no stones were present Immediately a flat dark object, about 1 in long, escaped It was picked up on the end of a glass sucker and proved to be an adult *Fasciola hepatica* The liver was not enlarged The common duct was washed out with sterile water, but no more liver flukes were seen A gum-elastic bougie passed without obstruction into the duodenum. A medium sized T tube was left in the common duct

Convalescence was uneventful The bile from the T tube and fæces were frequently examined, but no adult or immature flukes were found The T tube was removed at the end of three weeks The patient has since remained in excellent health.

Dr A C Hallowes, M O H for Leek, has provided the following figures obtained from the local abattoir over a period of a year

Animals inspected	
Cattle	2359
Sheep	3498
Total	5857
Bovine livers affected either wholly or in part by liver fluke	1150
Sheep livers affected by liver fluke	392
Total	1542

Livers affected = 26 3 %

These figures reveal a relatively high proportion of infected animals in this area, and it is not surprising that a case of human infection should be encountered Yet, so far as I can ascertain, this is the first case observed in North Staffordshire

The source of infection in this case was probably watercress or lettuce Beds of both exist at the patient's farm

SUBACUTE BACTERIAL ENDOCARDITIS CAUSED BY COAGULASE-NEGATIVE STAPHYLOCOCCUS ALBUS

HENRY MATTHEW
M B Edin , F R C P E
ASSISTANT PHYSICIAN, EDINBURGH ROYAL INFIRMARY

COAGULASE is an enzyme, elaborated by certain potentially pathogenic organisms, which can bring about rapid clotting of blood Its production by staphylococci is commonly employed in the laboratory to differentiate pathogenic from non pathogenic organisms of that group

Since at least twelve different techniques can be used to demonstrate an organism's ability to produce coagulase, it is not surprising that results vary considerably (Williams and Harper 1946) Despite this discrepancy the test is now generally regarded as the best single method of determining the pathogenicity of a staphylococcus (Cruickshank 1937, Fairbrother 1940, Jordan and Burrows 1941, Smith and Hale 1944) Topley and Wilson (1946) stated that the production of coagulase had not yet been established as a certain indicator of potential pathogenicity , but Browning and Mackie (1949) hold that one of the most constant properties of pathogenic staphylococci is their power to coagulate citrated blood

Bacterial endocarditis is rarely caused by *Staph albus* An incidence of 1% is given by Thayer (1931) and Perry (1936), who do not say whether the *Staph albus* produces coagulase or not When it is pathogenic, that organism would be presumed to be coagulase positive For a coagulase negative organism to give rise to subacute bacterial endocarditis is, though not unknown (Cunliffe and Gillam 1943), very uncommon

Two consecutive cases of subacute bacterial endocarditis admitted to a medical charge both had a coagulase negative *Staph albus* as the infecting organism They were also remarkably alike clinically The method used for testing for coagulase was that of Fisk (1940)

FIRST CASE

A boy, aged 18, admitted to hospital on Nov 24, 1948, gave a history of acute rheumatic fever in 1946, when he had been off work for fourteen weeks. He had made a full subjective recovery and had been working as an electrician in the mines and playing football energetically. Three weeks before admission he had developed an "influenza" like chill over the course of three days. This had been manifested by flitting joint pains, sore back, and pyrexia. The only other symptom has been the sudden onset of severe pain from time to time in the pulps of his fingers and toes. The acute features of the illness had only lasted three days but had been followed by asthenia and general pallor, which had caused him to be referred to hospital for blood examination. There was no recent history of acute staphylococcal skin infection, although he had a chronic acneiform eruption of the face, shoulders, and back.

---

* Since this note was submitted for publication a further case has been published by F D Murphy and K G Pascall (*Brit. med. J* 1950, i 647)

On *examination* he was a well built pale youth with acne of the face and shoulders; pulse rate 86, respirations 18 per min., temperature 99·4°F; moderate clubbing of the fingers and toes; Osler's nodes in two fingers. The enlarged heart showed very free aortic regurgitation and mitral stenosis; blood pressure 150/10 mm. Hg. The tender spleen was enlarged to two finger breadths below the costal margin. A recent retinal hæmorrhage was evident and red blood-cells were found in the urine. The sternum was tender. Hæmoglobin 70%; erythrocyte-sedimentation rate 40 mm. in 1 hour.

During *observation* for two weeks following admission, further pain of sudden onset in the finger pulps was complained of, and one more Osler's node appeared. Red cells were found in the urine without any casts or significant quantity of albumin. The spleen extended a further two finger breadths below the costal margin.

Blood-cultures.—During this period seven blood-cultures were done, and all grew a coagulase negative *Staph albus*, not unexpectedly reported as a contaminant. No other organisms grew; the blood was withdrawn by four different operators using different cleansing agents for the skin. Superficial and deep skin cultures did not grow organisms similar to the *Staph albus* repeatedly isolated from the blood. However, pus from an acne pustule and blood obtained from sternal marrow puncture both gave a coagulase-negative *Staph albus* similar if not identical to that obtained by blood-culture. The organism was penicillin sensitive with a coefficient of resistance of 1.

Serological reactions suggested that the patient's serum had a higher antibody titre for this particular *Staph albus* than had pooled serum, and that the staphylococcus in question was more readily checked in its growth by the patient's serum than were a random selection of staphylococci.

Diagnosis and Treatment.—The clinical diagnosis of subacute bacterial endocarditis was self-evident. It was considered that seven peripheral blood-cultures and one sternal marrow blood-culture all producing the same organism, together with the raised antibody titre, indicated that despite the absence of coagulase production the organism was pathogenic and had secured a hold on the heart valves. Treatment with penicillin 250,000 units three hourly (Christie 1949) was started. Two days later the blood-culture became negative and it remained so thereafter.

The *clinical course* was not so straightforward. Three days after the start of treatment the patient complained of pain and tightness behind the sternum spreading up to the left shoulder. The pain, persistent and crushing, was accompanied by dyspnœa and aggravated by coughing or taking a deep breath. It lasted with diminishing intensity for five days, during which time he was gravely ill. The pulse rate rose to 120 but there was no alteration in the blood pressure. Electrocardiographic recordings over this period suggested posterior myocardial infarction in the subepicardial layers. On the fifth day after the onset of pain, while the patient was still gravely ill, pericardial friction became audible to the left of the sternum and was soon evident all over the præcordium. With the appearance of the friction, his general condition improved, and he was soon free from pain and breathlessness and feeling stronger. As friction gave way to muffled heart sounds the improvement continued, the spleen regressed, and the amount of hæmoglobin rose by 15%. He experienced the sensation of well being and returning strength characteristic of the successfully treated case of subacute bacterial endocarditis. On Jan. 1, 1949, the nineteenth day of penicillin therapy, he died suddenly while sitting on a bedpan.

Necropsy carried out four hours after death, showed a much distended pericardial sac containing over 600 ml. of blood-clot and blood. The heart was opened aseptically (Green 1939) and cultures of the heart blood and valves were made. The blood was sterile, but the aortic valve yielded a coagulase negative *Staph albus* which proved later to be similar, if not identical, to the organism previously isolated. The grossly enlarged heart showed on naked-eye examination evidence of old standing rheumatic aortic and mitral disease. There were also present acute rheumatic vegetations along with further vegetations suggesting bacterial endocarditis influenced by penicillin therapy.

The spleen, weighing 700 g., was congested but showed no areas of infarction. There was no evidence of congestive heart failure in the liver. Section of the mitral valve showed inflammatory changes characteristic of healing subacute bacterial endocarditis together with rheumatic vegetations in which Aschoff nodules of recent formation were demonstrable. Organisms were seen beneath the fibrinous layers but it could not be definitely determined whether they were streptococci or staphylococci. The myocardium showed a few recent Aschoff bodies in addition to numerous large areas of focal embolic myocarditis placed chiefly immediately below the epicardium. This area beneath the epicardium was extremely vascular owing to intensive organisation and formation of new blood vessels. The age of the infarcted areas was in keeping with the clinical features. It was considered that rupture of certain of the vessels in this highly vascular area had caused the cardiac tamponade which was the immediate cause of death. Section of the kidneys showed focal embolic nephritis. Two small areas of infarction of about three and six weeks old were found in the brain.

SECOND CASE

A man, aged 41, had had rheumatic fever at puberty and sustained endocardial damage. His activities had not been restricted, and he served throughout the war at Dunkirk and the Malta siege in heavy anti aircraft batteries. He had remained well till six weeks before admission, when he noticed he was easily tired, slightly short of breath, and experiencing chills each evening. There was associated arthralgia in several joints with swelling and redness of the left ankle. Three weeks later he had painful pulps in two fingers which however might have been traumatic. He had had no recent dental infection or attention, and no skin lesion.

On *examination* he was ill nourished and had a temperature of 101·6°F; pulse rate 94; respiration 22 per min.; slight sacral œdema; moderate fresh pink clubbing of the fingers and toes; no petechiæ and no splinter hæmorrhages. His enlarged heart showed a free aortic regurgitation, the spleen was just palpable, and there were no red cells in the urine or other evidences of embolic phenomena. The sternum was tender; electrocardiography showed left-sided hypertrophy, with a very prolonged P–R interval of 0·3 sec. The erythrocyte sedimentation rate was 45 mm. in 1 hour, Hb 65%, blood pressure 120/50.

Blood-culture produced coagulase negative *Staph albus* on five occasions in five days. No other organisms were isolated, and no similar staphylococcus was obtained from superficial or deep skin culture. The coefficient of resistance to penicillin was 1.

Diagnosis and Treatment.—The clinical diagnosis was subacute bacterial endocarditis, due to coagulase negative *Staph albus*. Treatment with penicillin 250,000 units three hourly was started on the same day because the patient was experiencing tightness in the chest, pain in the left shoulder, and breathlessness.

Course.—That evening pericardial friction was audible to the left of the sternum. Electrocardiography showed evidence of subepicardial damage on the anterior surface of the heart. After a stormy forty-eight hours during which there was evidence of increasing congestive heart-failure and the pain and breathlessness persisted, the patient began to improve and his symptoms lessened. Digitalis, started cautiously, had to be discontinued after forty-eight hours—6 grains of the powdered leaf had been given—owing to a great increase in the number of dropped beats and further prolongation of the P–R interval. Neptal produced a good diuresis, and as in case 1, the crisis seemed over. Cachexia was rapidly dispelled and a feeling of well being induced, despite the persistence of pericardial friction over a wide area. Blood-cultures became negative as soon as penicillin was started. The pericardial friction disappeared after twenty six days, its place being taken by muffled heart sounds. The spleen was no longer palpable after eighteen days' penicillin. Improvement was maintained, and œdema was kept in abeyance with neptal 2 ml every third day On the thirty fourth day after starting penicillin the patient died suddenly without warning

Necropsy done twenty hours later showed the pericardial sac to be almost obliterated by old fibrous adhesions, but recent fibrinous pericarditis was also present The heart was opened aseptically, and heart blood and valves were cultured From the heart blood and the aortic valve a coagulase negative *Staph albus* corresponding to that previously isolated during life on blood culture was recovered The mitral valve showed the slight scarring of old rheumatic endocarditis The aortic valves showed long standing rheumatic changes and large vegetations typical of subacute bacterial endocarditis in addition to vegetations suggesting acute rheumatism The myocardium showed no macroscopic infarction The spleen was enlarged, weighing 440 g

Microscopically the place of the aortic valve was largely taken by thrombotic vegetations, but a few coccal organisms were seen their arrangement was quite haphazard, making it impossible to say whether they were staphylococci or streptococci The mitral valve showed old rheumatic scarring but also Aschoff bodies, which were assessed as having been present for about ten weeks—the duration of the present illness The pericardium showed low grade non specific subacute inflammation superimposed on old scarring No *bacteria were seen The myocardium contained Aschoff* bodies, many very old, some recent (about eight weeks old), besides very many areas of focal embolic infarction The infarcted areas were of varying ages, from weeks to 12-24 hours, they were considered sufficiently numerous and extensive to be the cause of sudden death

DISCUSSION

It is generally assumed that the production of coagulase indicates the pathogenicity of a staphylococcus

Two cases of subacute bacterial endocarditis are reported in which a coagulase negative *Staph albus* was repeatedly isolated from the peripheral blood, and in one patient from the sternal blood The cases demonstrated the classical features of subacute bacterial endocarditis, both clinically and post mortem The presence of pericarditis and pericardial effusion, however, calls for comment, because pericardial symptoms and signs are uncommon in endocarditis due to *Strep viridans* Thayer (1931), noting pericarditis in only 5 8% of cases of subacute bacterial endocarditis, draws attention to the importance of this sign in distinguishing bacterial from rheumatic endocarditis Pericarditis was present in 58% of his series of acute rheumatic endocarditis Matthew and Gilchrist (1949) also found pericarditis rare in subacute bacterial endocarditis, it being absent clinically in all 40 of their cases and present post mortem, and that only to a minor degree, in but 1 of 15 cases so examined

In the cases here reported the most striking clinical feature was pericarditis followed by pericardial effusion The pericarditis was demonstrated post mortem not to be rheumatic or infective in origin but the result of very numerous and extensive areas of myocardial infarction in the subepicardial region

Despite apparent improvement under penicillin therapy, both patients died after a remarkably similar clinical course A coagulase negative *Staph albus* was recovered post mortem from the heart valves in each case, and organisms, possibly staphylococci, were seen in the sections of the valves

There can be little doubt that the infecting organism in these two cases of subacute bacterial endocarditis was a *Staph albus*, despite its inability to produce coagulase It is therefore important that, when such an organism is repeatedly isolated from the blood of a patient suspected to have subacute bacterial endocarditis, it should not be discounted as a contaminant but regarded as the infecting organism, and its coefficient of resistance to penicillin should be estimated

In such cases a clinical course featuring multiple myocardial infarction with subsequent pericarditis with effusion may be anticipated

The presence of Aschoff bodies of recent formation further supports the view that subacute bacterial endocarditis is often superimposed on a valve in the presence of an active rheumatic carditis (MacIlwaine 1947, Matthew and Gilchrist 1949, Von Glahn and Pappenheimer 1935) rather than on an inactive chronic valvular lesion

The prognostic significance of such a relation between active rheumatic carditis and the superadded infection (Matthew and Gilchrist 1949) is also borne out, a fatal issue being common where the history suggests a concomitant acute rheumatic infection

SUMMARY

In two cases of subacute bacterial endocarditis the infecting organism was a coagulase negative *Staph albus* Pericarditis was a striking feature, being produced in both cases by multiple areas of focal embolic infarction of the myocardium The myocardial damage was sufficiently extensive to be the cause of death

The patients were under the care of Dr A Rae Gilchrist, to whom thanks are expressed for guidance in the preparation of the report *The bacteriological investigations were* made by Dr T B M Durie, and the autopsies by Dr Rhaney

ACUTE INFECTIOUS LYMPHOCYTOSIS IN AN ADULT

B Malamos
M D, D T M

A Stamatelakis

Most hæmatological textbooks state that lymphocytosis is characteristic of lymphocytic leukæmia and infectious mononucleosis (glandular fever), it also occurs in pertussis, where it may be as high as 145,000 per c mm (Pearson and Newns 1937), in mumps, in some chronic forms of tuberculosis, in convalescence from infections, and in diseases of endocrine origin In most of these conditions pathognomonic symptoms facilitate the differential diagnosis, but when they are not present lymphocytosis suggests either lymphocytic leukæmia or infectious mononucleosis

Smith (1941) described, under the title of "acute infectious lymphocytosis," a benign condition in children, characterised by leucocytosis and a pronounced increase in the number of lymphocytes This condition seems to be distinct from infectious mononucleosis Wintrobe (1946) said that some 52 cases had been reported and added 2 of his own Vomiting, irritability, fever, abdominal signs and symptoms, occasionally signs of involvement of the nervous system, and a morbilliform rash have been observed, but in *many* cases there have been no symptoms whatever In Smith's 1941 experience, infection of the upper respiratory tract has been a common finding Symptoms, when present, have not lasted more than a few days The leucocytosis has persisted, on the other hand, for three or more weeks Leucocyte counts reaching 40,000 per c mm are common,

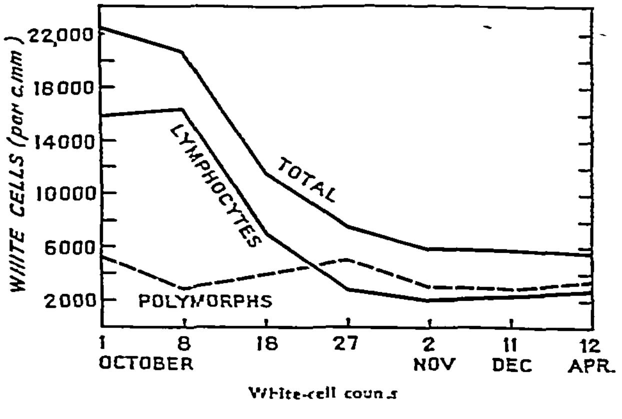
Nov 11, 1949							7000	51	4	3	42		

and counts even over 100,000 per c.mm. have been reported. The great majority of the cells (60–92%) have been "adult" small lymphocytes, not unlike those seen in chronic lymphocytic leukæmia. Lymph-node enlargement and splenomegaly are generally absent. No anæmia or thrombocytopenia has been observed. Wintrobe (1946) reported that the sternal marrow, in the few cases examined, showed an increase in the percentage of the lymphocytes (30–40%), which were of normal type. The lymphocytosis in the marrow reached 86% in Duncan's (1943) case. These results were not confirmed by Lorenz et al. (1946) and Leitner (1949) thinks that some cases may have been virus pneumonias or that the high lymphocyte percentage was due to an admixture of blood. Biopsy of the lymph nodes revealed degeneration of the lymph follicles, with striking proliferation of the reticulo-endothelium (Smith 1944). The heterophil agglutination test has been uniformly negative. In 4 cases serological reactions were negative for lymphocytic choriomeningitis and for influenza A and B viruses. The disease seems to be both infectious and contagious, with a possible incubation period of 12–21 days. The outcome has been uniformly favourable.

Most of the cases described have been in children, and only very few were seen in young adults (Duncan 1945, Finucane and Philips 1944, Wintrobe 1946). From Greece only 1 case has been reported, in a girl aged 3½ years (Nimos 1948).

Smith (1944) distinguishes two types of the disease: (1) acute infectious lymphocytosis, which is characterised by a transient unexpected hyperleucocytosis, with a relative and absolute lymphocytosis, and not associated with any recognisable symptoms or signs; and (2) chronic infectious lymphocytosis, a more common type which follows infections of the upper respiratory tract and is characterised by low-grade fever and often associated with symptoms, such as anorexia, pallor, tiredness, and para-umbilical pain. Smith considers that both types are separate clinical entities, although there is some evidence that they may be related. He believes that the cause is probably a virus.



White-cell counts

We report this case of acute infectious lymphocytosis because of the difficulty in diagnosis and the uncommon age of the patient.

CASE-RECORD

A woman, aged 25, had been married in October, 1947, and delivered of a healthy girl on July 16, 1948. In the previous year, before the onset of her illness, she felt tired, which was in contrast to her usual activity. She lost her appetite and in a few months her weight fell by 1½ st. At the end of her pregnancy it rose again to its original level.

Her mother returned from a voyage in the middle of September, 1948, and noticed that her daughter was looking pale and tired. After thorough questioning the patient mentioned slight abdominal pains on Sept. 11 and 12 and lassitude in the last few weeks. She had had no fever. After delivery she had menstruated normally on Aug. 28 and Sept. 22, 1948. The mother insisted on a medical examination. The obstetrician's findings were negative. The specialist in medicine thought that the liver was slightly enlarged. No other physical signs were detected. A blood-count on Oct. 1, 1948, showed red cells 4,240,000 per c.mm., Hb 80%, colour-index 0·94, white cells 22,600 per c.mm. (basophils 3%, eosinophils 2%, polymorphs 24%, lymphocytes 71%). Since there had been no pertussis or endocrine disease in the history, this blood-count suggested chronic lymphocytic leukæmia, so the sternal marrow was examined. On Oct. 5 it was found to be normal except for a slight increase in the proportion of lymphocytes (20%), which were mature and normal. On Oct. 6 the patient's basal metabolic rate was found to be −1%, radiography of her chest was normal, and her mediastinal lymph glands were not enlarged.

When I saw her for the first time on Oct. 8, she still complained of lassitude and looked pale and tired. The physical examination was negative. No enlarged lymph glands were found. The spleen and liver were normal. There was no abdominal tenderness. Blood-pressure 120/60 mm. Hg, pulse-rate 60 per min. Weight 58·0 kg. No fever.

Investigations.—A blood-count on Oct. 8 showed red cells 4,400,000 per c.mm., Hb 84%, colour-index 0·95, white cells 21,000 per c.mm. (basophils 0·5%, eosinophils 3%, polymorphs 15%, lymphocytes 78·5%, monocytes 2·5%, plasma cells 0·5%). The lymphocytes were small adult forms with normal nuclei and cytoplasm, 30% with azurophil granulation. On Oct. 18 the white-cell count had fallen to 12,000 per c.mm., and the lymphocytes to 62%. The lymphocytes were normal, 26% with azurophil granulation. Blood uric acid 9·7 mg. per 100 ml. Platelets 225,000 per c.mm. On Oct. 19 a sternal puncture showed bone-marrow absolutely normal with 7·5% lymphocytes. Further blood-counts are shown in the accompanying table. The erythrocyte-sedimentation rate (E.S.R.) on Nov. 2 was 10 mm. in first hour, 30 mm. in 2 hours. A Paul-Bunnell-Davidson test was negative.

Progress.—The patient left in November, 1948, for the Côte d'Azur. She felt better there, complaining occasionally of nausea. A blood-count in France showed no increase in the number of leucocytes and the proportion of mononuclear elements was only slightly above normal. She returned to Athens in December, 1948, feeling less tired.

Dec. 11: urine normal; blood-sugar 0·86 g. per 100 ml.; blood-cholesterol 1·70 g. per 100 ml.; serum-bilirubin 0·56 mg. per 100 ml.; E.S.R. 5 mm. in first hour, 13 mm. in 2 hours; white cells 5700 per c.mm. (lymphocytes 38%, 35% with azurophil granulation). Dec. 23: no protozoa and no ova in stools. Dec. 24: Paul-Bunnell-Davidson test negative (limit 1/14).

Follow up —In a blood count on Nov 11, 1949, the leucocytes totalled 7000 per c mm (lymphocytes 42%) *

Throughout the blood examinations the lymphocytes were found normal in size and shape with normal nuclear and cytoplasmic structure The number of lymphocytes with azurophil granulation was always within normal limits Erythrocytes and platelets showed no abnormal changes

DISCUSSION

The first blood count in the present case was done only because the patient was looking pale and complained of lassitude At the clinical examination the findings were negative The high leucocytosis (22 600 per c mm) with the high relative and absolute lymphocytosis (71%), and the absence of any history of an acute or chronic infectious disease or a disease of the endocrine glands, suggested chronic lymphocytic leukæmia But this diagnosis was improbable because (1) the spleen and lymph glands were not enlarged , (2) the bone marrow contained a normal percentage of lymphocytic cells (in published reports few cases of lymphocytic leukæmia are described without a lymphocytosis in the bone marrow) , and (3) only normal adult lymphocytes were found in the peripheral blood and in the bone marrow, without any pathological alterations of the nuclei or degeneration of the cytoplasm Normal azurophil granulation in 26–40% of the lymphocytes is a finding which has not been reported in lymphocytic leukæmia Naegeli (1931) had examined thousands of lymphocytes in such cases without finding any azurophil granules, except in one rather benign case where he found azurophil granules in 14% of the lymphocytes

Infectious mononucleosis (glandular fever) was excluded because (1) all the lymphocytes were small adult forms, and (2) the clinical signs were absent

The diagnosis of acute infectious lymphocytosis was confirmed by the progress and the further hæmatological examinations (see table and figure) In a month the leucocyte count and the absolute and relative lymphocyte counts were again normal

We believe that this case belongs to the type called by Smith (1941) acute infectious lymphocytosis, where clinical pathological signs are absent and the disease starts suddenly, without prodromal symptoms In this type the blood changes are found during a routine blood examination This sudden discovery of the blood changes without clinical signs supports the diagnosis of acute infectious lymphocytosis

Paul Bunnel Davidson tests were negative on two occasions , this result agrees with the findings of other workers The negative Paul Bunnel Davidson test in acute infectious lymphocytosis makes it highly probable that this disease is a separate clinical entity and not a form of infectious mononucleosis (glandular fever)

Acute infectious lymphocytosis is usually seen in children Our case (patient aged 25) is one of the few exceptions in young adults

SUMMARY

Acute infectious lymphocytosis is reported in a woman aged 25 The case was characterised by a high leucocytosis and a relative and absolute lymphocytosis, with no clinical symptoms or signs (no enlargement of lymph nodes, no splenomegaly) The differential diagnosis, especially from lymphocytic leukæmia, is discussed

The outcome of the illness was favourable, the blood picture returning to normal in a month The case was followed for over a year

THE "DUFFY" ANTIBODY AND HÆMOPHILIA

J D JAMES
M R C S
DIRECTOR

G PLAUT
M D Heidelberg
SEROLOGIST

NORTH LONDON BLOOD TRANSFUSION CENTRE

THE original antibody anti Fy^{a}, reported by Cutbush et al (1950), was found after a transfusion reaction in a hæmophiliac who had received previous transfusions the second example (Ikin et al 1950) was found in a patient with a bleeding peptic ulcer who had also had previous transfusions Two further examples of anti Fy^{a} have since been reported in a hæmophiliac by Van Loghem and Hart (1950), and in a patient undergoing prostatectomy by Rosenfield et al (1950)

We are now reporting this rare antibody in another hæmophilic patient, who had the following history of transfusions

1940 and 1942 Transfused with father's blood

1944 and 1945 Transfused with whole blood from unknown donors (These transfusions stopped the bleeding)

March, 1950 Transfusion with blood from a Red Cross donor produced a reaction

July, 1950 Infusion of fresh plasma and fibrinogen had no beneficial effect

August, 1950 Transfusion of about 300 ml of father's blood produced a reaction

We were then asked to cross match blood from our bank, and in so doing discovered anti Fy^{a} in the patient's blood , this was only demonstrated by the indirect Coombs reaction Our finding was confirmed by Dr A E Mourant The patient's genetic formula is group O, R$_{1}$R (CDe/cDE), MN, S + ve, P + ve, Lu − ve, Le^{a} + ve, Le^{b} − ve, Kell − ve His father's is group O, R$_{1}$R$_{2}$ (CDe/cDE), Fy^{a} + ve

We have since tested eight hæmophiliacs whose names were kindly supplied by Dr R G Macfarlane and Dr C Merskey, of Oxford, and found that three were Fy^{a} − ve and five Fy^{a} + ve , no anti Fy^{a} antibodies were demonstrated

It is recognised that numerous transfusions may lead to the production of one or more antibodies, but the fact that three of five people in whom anti Fy^{a} antibodies have been reported were hæmophiliacs suggests that the relationship between this antibody and hæmophilia deserves further investigation

We wish to thank Dr K E Harris for some clinical details and Dr M Maizels and Dr P L Mollison for providing serum for the investigation

SIMPLE AND RELIABLE TEST FOR BILE-PIGMENTS IN URINE

JOHN INGHAM
F.R.I C
BIOCHEMIST TO THE MEDICAL UNIT, SCHOOL OF MEDICINE, CARDIFF

FOR ordinary purposes the present tests for urinary bile pigments are satisfactory, but their sensitivity is limited, so they will not detect bile in minute quantities A simple and reliable test, sensitive enough to detect even a trace of bile pigments, would be helpful to the clinician, especially in the investigation of possible cases of infective hepatitis Such a test is described here The principle of this is concentration of the bile pigments by chromatographic adsorption in a gel mat, followed by detection of the pigments in the mat by means of a special reagent

Stock Colloidal Solution —Place 1000 ml of distilled water in a 2 litre conical flask add 50 g of alum (ammonium), and heat gently until dissolved Cool to about 40°C and add, little by little and shaking after each addition, 5% (*v/v*) solution of ammonium hydroxide until the contents are markedly alkaline to litmus Then add 1% aqueous solution of alum (ammonium) until the contents are slightly acid to litmus Allow to stand overnight Next day, pour off most of the supernatant clear liquid, add 500 ml of distilled water, shake well and leave overnight On the following day pour off about two thirds of the supernatant clear liquid The remaining colloidal solution is ready for use

Reagent —Dissolve 26 g of trichloracetic acid in 100 ml of distilled water and add 1 g of pure ferric sulphate $Fe_2(SO_4)_3$ This reagent resembles Fouchet's but contains a little more trichloracetic acid, and the use of ferric sulphate in place of the ferric chloride makes the solution colourless instead of faintly yellow The reagent is also slightly more sensitive to bile pigments than Fouchet s

The Test —Half fill a 2½ inch ribbed glass funnel with absorbent white cotton wool and press this down gently Shake the stock colloidal solution, to ensure a uniform thickness, and pour some over the cotton wool and allow it to filter through until a smooth gel mat forms on the surface of the wool. Then fill up the funnel with the urine to be tested and as the urine filters through all the pigments will be retained on the gel mat The filtrate will be colourless if the gel mat has been properly formed and is efficient

Now add a few drops of the reagent to the gel mat, and if even the minutest trace of bile pigment is present the mat will turn a clear bright emerald green which will not fade for some hours (The reagent oxidises the bilirubin to biliverdin.) The more bile pigment that is present the more intense will be the green colour Quantitative estimations, if desired can be carried out by placing standard solutions of bilirubin on other gel mats similarly constructed, adding a few drops of the reagent, and comparing the colours

Over 300 specimens of urine containing all kinds of pigments other than bile pigment have been tested by this method and no false positive results have been detected Comparison with most of the well-known tests for bile pigments—tincture of iodine, Gmelin's nitric acid, Franke's methylene blue, Harrison's barium chloride, Watson's modification of Harrison s, and Murray Franklin's—has shown that the test described here is much more sensitive and therefore reveals the presence of minute amounts which cannot be detected by the others

---

"   Ether is unpleasant it is irritating, it is toxic, and it is explosive   And yet ether has one supreme advantage as an anæsthetic agent—it does not depress respiration. Even though a patient may splutter and kick and get full of mucus, he still breathes For this reason it is my firm conviction that unless a doctor makes himself familiar with the method of controlling respiration, and has available the necessary apparatus he should not be tempted into using the new easily administered anæsthetics and he should make old fashioned ether the mainstay of his anæsthetic practice"—H R GRIFFITH, *Canad med Ass J* 1950 63, 533

MEDICAL SOCIETY OF LONDON

Unexpected Death Following Operation

A DISCUSSION on this subject was held on Jan 8, with Dr A. H DOUTHWAITE, the president, in the chair

Dr I W MAGILL said it was essential to differentiate between death due to anæsthesia and death occurring from other causes while the patient was under the influence of, or recovering from, an anæsthetic Modern anæsthetics had not led to a reduction in deaths under anæsthesia, but one reason for this was that with modern techniques many patients who would formerly have been considered inoperable were now given their "only chance" through surgery A survey of 250 cases showed that abdominal surgery was the chief source of postoperative death, and as a rule more than one grave pathological condition was present Investigation of the cause of death should be very thorough, and sometimes the anæsthetist was alone capable of giving the answer

The volatile and gaseous anæsthetics formerly used were, in safe doses, not respiratory depressants, and their action was reversible The modern solid anæsthetics, on the other hand, did depress respiration With the volatile anæsthetics there was a time lag before an overdose could be given but when giving an intravenous injection it was fatally easy to give more than enough Care of respiration was the first responsibility of the anæsthetist A recent investigation of 112 cases showed an incidence of nearly 20% of regurgitation and aspiration by which gastric contents entered the lungs, but in the hands of an experienced anæsthetist this should never happen The endotracheal tube had proved its value. When respiration was depressed or absent, ventilation of the lungs must be taken over by the anæsthetist. Effective control using the rebreathing bag, was easy in the operating-theatre, but care must be taken to ensure that the ventilation was adequate—in other words the young anæsthetist must be taught to concentrate on the patient. Spontaneous respiration must be restored before assistance was ended, but often it was insufficient at first and therefore there was a definite risk in the immediate postoperative period Other conditions being satisfactory the anæsthetist had a considerable responsibility for the postoperative state of the patient Pulmonary embolism was preventable, and it was for the anæsthetist to ensure that the patient's posture on the operating-table was such as to ensure an unimpaired venous return For example, accidental pressure on the calves of the legs in the Trendelenburg position might cause embolism

The physiological balance of each individual varied and it was essential to assess the patient s ability to withstand the anæsthetics and the surgery During the operation wide blood pressure variations should be avoided and blood lost should be replaced concurrently It was the duty of the anæsthetist to indicate the necessity for this when it arose. A recent development in surgery was deliberate lowering of the blood-pressure by giving pentamethonium iodide Dr Magill did not know of any fatalities from this, and it might be that the attitude towards the significance of low blood-pressure needed revision But it seemed fair to infer that a systolic pressure of 50–60 mm Hg did not enhance the viability of the cerebral centres

The position of the patient after operation must be such as to ensure respiration and easy expulsion of vomitus Dr Magill favoured the postoperative recovery room, fully equipped and in charge of a properly qualified person, such as a registrar, to which the patient went for 24 hours When all anæsthetics were administered by specialists, he concluded, then and only then would there be hope of further reduction in the fatality rate

Dr C KEITH SIMPSON pointed out that the coroner had a double duty He had to see not only that the anæsthetist and surgeon were satisfied, but also that the relatives were conciliated, he was the one man—especially since the change in the administration of medicine—who stood between the public and the ordinance of the law The arrangement whereby the coroner ordered an investigation into the cause of any death before full recovery from an anæsthetic could be satisfactory only if the medicolegal pathologist, the anæsthetist, and the surgeon discussed the matter in detail before the post mortem examination The improvement in the standard of anæsthetics in the last ten years had been remarkable, and of unexpected deaths following operation 75% had little to do with the anæsthetist or the surgeon Of course any operation (however trivial) and any anæsthetic (however well administered) were adverse factors They could not be advantageous except in the occasional (blue) patient who was previously suboxygenated An analysis of 500 cases showed death to be due to natural causes in 279 (56%), to operative shock—resulting from quite restrained surgery—in 149 (30%), to complications of anæsthetic risks in 40 (8%), and to overdosage or bad choice of anæsthetic in 32 (6%) In the latter classes some 85% appeared avoidable

Death from natural causes might be due to cardiorespiratory limitations not recognised before the operation A patient who died under a dental anæsthetic had been examined the night before, death was found to be due to a fresh thrombosis which might well have occurred during the night Premedication must not be overlooked as a source of death especially when it was delayed or repeated With some anæsthetic drugs, there was clearly a risk, however skilfully they were used The reaction to a barbiturate varied not only from one person to another but also in the same person at different times, less than 0 5 g of thiopentone might precipitate death Overdosage was largely a matter of the past, but even today a skilled anæsthetist might go on administering an anæsthesia causing considerable suboxia for far too long a period Dr Simpson quoted cases of death which had taken place when the operation was prolonged during teaching The kind of operation most commonly responsible for death was the one undertaken to give the patient any chance of life at all or life in any tenable form Modern intrathoracic surgery, for instance, came into this category there was bound to be a risk of death, which would, however, be recognised by the coroner, and also by the relatives, where the facts had been explained to them

No patient should pass out of the hands of the anæsthetist until fully recovered from the anæsthetic Particularly dangerous was the system, still in force in some hospitals, by which a male attendant or even a porter took the patient back to the ward Quite often a preventable death—e g, after tonsillectomy—occurred on the way

When fat or air embolism was overlooked as a possibility, death might be ascribed to the wrong cause A careful necropsy technique was essential for the discovery of air embolism, and where this condition was suspected the surgeon and anæsthetist should be present and the investigation should start from the point where it was thought that the air might have entered A cause of death which it was impossible for the pathologist to discover on his own was reflex vasovagal inhibition This might arise from the skin, for example the stripping of a dressing might produce a fatal reflex, and this was one reason why some painful dressing should be done under anæsthesia Other sources of reflex vasovagal inhibition were stimulation of sympathetic branches on the cardiac sheath or the aortic bodies, sudden disturbance of large masses in the abdomen, tension on the peritoneum, or urethral and other pelvic instrumentation—especially under light anæsthesia

Dr G S W **Organe** thought it was important not to attempt too much in operations on old people

Dr E B **Strauss** reported on the electrical stimulation of respiration in patients where respiratory failure occurred during electroconvulsion therapy or during narco analysis with barbiturates The apparatus devised at St Bartholomew's Hospital consisted of a box condenser with two small round electrodes of the type used in E C T These were applied to the frontotemporal region, giving a steep fixed wave of current of low amperage It was found that a current of 1–2 mA with a pulse width of 50 kilocycles, applied for 2–6 minutes, was very efficacious

Mr **Michael Smyth** said that a useful means of artificial respiration which the surgeon could adopt was to lean across the table and intermittently compress his chest against the patient's

Mr **Zachary Cope** had not seen a death during an operation in which there was controlled respiration, but was it possible for controlled respiration to take place for a long period without damage to the constitution of the patient?

Mr E W **Riches** paid tribute to the older type of anæsthetist who always visited his patient the day before operation He agreed that a skilled attendant must accompany the patient back to the ward, and stressed the importance of proper lighting in the lift, he knew a case in which death took place simply because the lift was ill lit

Mr W **McKim McCullagh** said that deaths among babies born by cæsarean section under gas and air anæsthesia were 5%, and over half of these were healthy babies He believed that deaths from pulmonary embolism, of which the gynæcologist saw many, could be prevented by a blood-count before the operation If the blood state was good, there was no need for physical exercises, such as having the patient walk about the day after the operation

Dr T **Jenner Hoskin** said that even a person with a bad heart could stand an operation, provided the anæsthetist knew he had a bad heart to deal with

Mr S M **Cohen** asked whether there was such a thing as neurogenic shock under anæsthesia, or was death due to blood-loss alone? If a patient with thrombophlebitis had been put to bed, operation might precipitate a blockage, hence, if it was not possible to operate at once, it was better to postpone the operation for ten days The same applied to fractures of the neck of the femur it was the rule in Edinburgh to manipulate within two days or wait ten days before operating

Mr **Guy Blackburn** said that controlled respiration made it possible for surgery to go on into the afternoon and evening and he wondered whether that had made some surgeons a little dilatory To reduce the incidence of unexpected deaths it was necessary to pay more attention to the preparation of the patient having an emergency operation Curare had often been blamed for postoperative deaths, but it had enabled the surgeon to do things he could not attempt before There was a general tendency to dispense with spinal anæsthetics because unexpected deaths were more frequent with them than with other anæsthetics

Sir **James Walton** said that anæsthetics today were so complicated that no one would dare to handle them who was not a specialist He did not accept the contention that old people could stand operations as well as young ones He used to tell his house surgeons that what they had to do was to make the patient comfortable So often, when called out, he had found the patient arrayed in tubes, and had said "Take those things out, and let him have a night's sleep!"

The **President** thought the artificial distinction between medicine and surgery which was growing up, starting in student days, was wrong He was quite sure that if there was closer collaboration between physicians and surgeons something could be done to reduce postoperative mortality

Dr **Magill**, in reply, said that if a patient did not respond to 1 5g of thiopentone he concluded that any more would be an overdose and he had recourse to other methods Prolongation of the operation was a cause of death, and in that respect there was a certain complacency among young surgeons In some hospitals the bed was brought into the theatre, thus eliminating one lifting of the patient—a possible source of embolism A competent anæsthetist always visited his patient before the operation, or if that was not possible made an assessment on a careful report Dr Magill urged care in the administration of sedatives after operation In his opinion, open ether was not "dead"

Dr KEITH SIMPSON said he had not yet seen a death from C5 or C6 It was some twelve years since he had seen a death from "ether convulsions" possibly because of improved standards of anæsthesia Though there was a decrease in culpable anæsthetic deaths, the number of cases succumbing was maintained by the advent of onerous new surgical procedures The advantages of quick gentle surgery were still quite plain

New Inventions

INSTRUMENTS FOR SUPRAPUBIC EXPOSURE OF PROSTATE AND BLADDER NECK

THE bladder retractor shown in fig 1 (A) has a posterior blade in two parts, so that the lower half can be lengthened or shortened according to the depth of the bladder base The extra-long posterior blade (B) is supplied for use in unusually voluminous bladders

The prostatic-bed forceps (C) has special teeth to enable the surgeon to get a firm grip of any part of the prostatic bed After a wedge resection different parts of the raw surface can thus be brought successively into view and any spurting vessels quickly dealt with

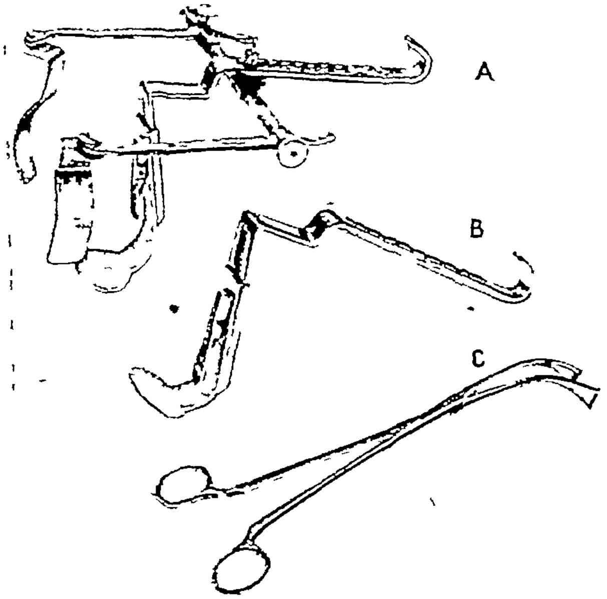

Fig 1

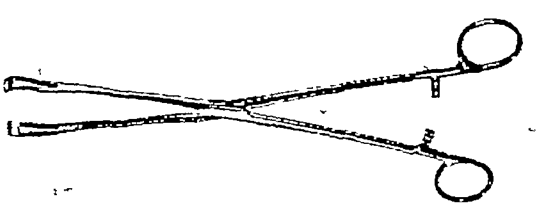

Fig 2

The bladder-neck forceps (fig 2) has the same kind of teeth With this instrument the posterior margin of the internal urinary meatus can be gripped and pulled firmly into view before diathermy resection of a wide portion of a fibrosed bladder neck is undertaken

The instruments were made to my specification by Allen & Hanburys Ltd , of London, W 1

London W 1 H P WINSBURY-WHITE, F.R.C.S

Reviews of Books

Radiation Therapy in the Management of Cancer of the Uterine Cervix

SIMEON T CANTRIL, M D , director, Tumor Institute of the Swedish Hospital, Seattle, Washington Springfield Ill Charles C Thomas Oxford Blackwell Scientific Publications 1950 Pp 200 36s

THIS is a thoroughly good survey of the progress and limitations of radium and X-ray therapy in treatment of carcinoma of the cervix In the midst of an overwhelming mass of work published on this subject, it is refreshing to meet with so clear and concise an evaluation Dr Cantril describes the basic principles which have evolved from the Swedish and French schools of radiotherapy Not all will agree with his statement that the great majority of cervical cancers arise in the endocervical canal, but all will share his view that from the standpoint of curability the cytological differentiation of the growth matters less than the anatomical extent of the disease when the patient is first seen He rightly deprecates any rigid adherence to a routine method of radiation therapy Success is achieved by building up the patient's resistance and adjusting the radiation treatment to suit the individual case The Stockholm, Paris, and Manchester techniques are clearly described, and the section on the role of X rays in the treatment of carcinoma of the cervix gives much useful information on the choice of techniques, and on combinations of radium and X-ray dosage Failures increase with the extent of the disease when treated Parametrial spread to lymph-nodes is the main cause of failure, and presents a problem which cannot be resolved by dosage alone Reviewing the results of surgical treatment of cervical carcinoma obtained by Fauré, Bonney, Taussig, Meigs, and others, Dr Cantril concludes that surgery, even in the best hands, is not likely to increase the survival-rate of patients in the early clinical stage

Radiation dosimetry in terms of "tissue dosage" was introduced by the Manchester school, and expresses tissue dose in rontgens The tissue dose can be added at a selected point, and is contributed by both the intracavitary radium and the external X-ray therapy Dr Cantril compares pelvic dosimetry obtained by other techniques and points out that—though precision is the aim—accurate calculation of dosage has limitations when applied to the patient Not only is it dangerous, but it is often futile, to push the dose in the more peripheral zones of the pelvis to a predetermined "effectual" dose In the living subject measures are at best an estimation precision depends upon the care with which they are made

The Book of the It

GEORG GRODDECK Translator V M E COLLINS London Vision Press 1950 Pp 301 15s

Exploring the Unconscious

GEORG GRODDECK. Translator V M E COLLINS London Vision Press 1950 Pp 224 12s 6d

IT was nothing new in the history of medicine when Groddeck proclaimed his belief that an intangible and unknown force directs everything—physical and mental—that happens in the human individual instead of calling this force the "It," after Nietzsche, he might have called it the Archaeus after Van Helmont, or even the entelechy after a greater predecessor He seems, however, to have had little awareness of the strength and the weakness of his philosophical position, but to have pushed on, after his preliminary work in physiotherapy, with the application of some Freudian tenets to the explanation and treatment of physical disease Naïve in his theorising—and bold, even for a psychoanalyst, in his use of symbolism—he went much further than Freud in attributing somatic disease to unconscious forces The Book of the It," here excellently translated, expounded his views in a series of letters, addressed to a sympathetic woman friend The literary form he chose suited his thought very well there was no need for systematic exposition or argument, and he could pile illustration on illustration, and make frequent use of the personal note This personal note appears also, of course, in the autobiographical fragments reproduced in *Exploring the Unconscious* from these we learn enough to understand his violent repudiation of orthodox medical beliefs, and to recognise his lifelong anti-intellectual bias In these and particularly in his disquisitions on the " belly-mind " he gives the English reader cause to recall D H Lawrence Besides some etymological speculations, there is in *Exploring the Unconscious* a psycho-analytical examination of *The Ring Faust*, and *Peer Gynt*—which is, however, less distinctive than the section on unconscious factors in organic processes His experience here had been heartening " I find that in obstinate organic cases of whatever nature, a psycho analytical examination is always useful and may prove essential to improvement To the best of my judgment chronic organic disease yields to psycho analytic treatment more surely and quickly than do the neuroses " The same however, might be said regarding the response to non psycho-analytical psychotherapy

Principles and Practice of Rehabilitation

Editor HENRY H KESSLER, M D, PH D London Henry Kimpton 1950 Pp 448 63*s*

THE 21 authors of this book are American surgeons, physicians, and psychologists who are engaged in treating the disabled Every branch of their vast subject is covered, and, on the whole, covered well Apart from the surgical and medical aspect, emphasis is placed on the need for a team spirit among all who work to make the handicapped person use fully the powers he still possesses, to place him in employment, and give him independence

The Antihistamines

Their Clinical Application S M FEINBERG, M D, associate professor in the department of allergy, North western University Chicago, SAUL MALKIEL, M D, PH D, assistant, R FEINBERG, M D, assistant Chicago Yearbook Publishers 1950 Pp 291 $4

THIS book sets out all the known clinical uses of the anti-histamines The experimental section has purposely been kept to a minimum, while the clinical application has been well covered Much of the evidence that histamine plays an active part in allergic reactions is inferred A drug which protects a guineapig from a normally lethal dose of histamine could well be called antihistaminic In man, however, these new drugs were found to have many beneficial effects unrelated to their antihistaminic activity The search for a new compound or a new combination of drugs which will give the minimum side effects with the maximum benefits continues An annual business of $100 million in America constitutes sufficient impetus for the manufacturers to look for new cold cures, new seasickness remedies and new cures for many unrelated complaints Written essentially for the American reading public the book does not include all the common English names for the various compounds Nevertheless it can be recommended to all who require a small reference work on the clinical uses of such drugs

Treatment of Uremia by Dialysis and Other Methods with Special Regard to the Principles and Scope of Intestinal Dialysis

E E TWISS physician, Municipal Hospital, Kampen, Holland Rotterdam Drukkerij M Wyt & Zonen 1950 Pp 209

THIS book is the third of a series, published from the Kampen Municipal Hospital, dealing with the treatment of uræmia by dialysis methods Kolff's thesis [1] on the artificial kidney was the first, Kop's thesis [2] on peritoneal dialysis the second, and this is the third The published work on dialysis methods in general is reviewed briefly and that on intestinal dialysis in detail After considering the anatomy and physiology of the intestine in this context, Dr Twiss deals with his own experiments, made on dogs, on the composition of dialysing fluids and the efficacy of dialysis through the intact intestinal wall The technique of intestinal dialysis in humans is described, including the method in which an isolated intestinal loop is used The results in 11 patients are evaluated

Intestinal dialysis seems to be a practicable method of correcting many of the disturbances in uræmia and the technique of dialysis through an isolated intestinal loop shows some promise in patients with severe and irreversible renal lesions It is of interest that Twiss was able to keep a virtually anuric patient alive for 46 days by this method

My Life in Three Counties (London Christopher Johnson 1950 Pp 247 15*s*)—Dr Pooler's roving mind and eye find ample scope in his latest venture, and he writes in his usual straightforward and unaffected style revealing his warmhearted humanity and wholesome sense of humour. The story of his early days in his own county of Shropshire is particularly delightful, and the numerous illustrations add a charm to the book

Urological Surgery (2nd ed London Henry Kimpton. 1950 Pp 855 £4 15*s*)—Prof Austin Dodson s book is already known as one of the finest expositions of operative urological surgery Several experts in particular fields—among them Dr Leon Howard on renal tuberculosis—have shared in this edition, and the work has benefited Illustrations are good and clear But as earlier criticisms have been met, it is a reviewer s duty to offer new ones Many would wish for a more detailed account of the operation of total cystectomy, no mention is made of the simple retropubic excision of congenital valves of the posterior urethra, and retropubic prostatectomy, despite its increasing band of adherents is rather summarily dismissed and poorly described Nevertheless the work maintains its place in the first rank

Practical Neurological Diagnosis (4th ed Springfield, Ill C C Thomas Oxford Blackwell Scientific Publications 1950 Pp 268 37*s* 6*d*)—Prof R Glen Spurling s little book, written for neurosurgeons, naturally has many omissions disturbing to physicians Moreover the structural divisions of the nervous system (as opposed to its function) receive greater attention than in medical texts. But it may be supposed that the neurological surgeon is interested in the diagnosis of conditions which do not require ventriculography if only to minimise the use of that distressing aid to diagnosis Dr Spurling says that ' lateral hemisection of the cord (Brown Séquard syndrome) occurs most frequently as a result of stab or gunshot wounds, a view which must be based upon highly selected material Again, the whole question of double vision as it affects neurological diagnosis is confined to 17 lines of print, while a chapter on radiological diagnosis is long, full and excellently illustrated There can surely be no neurosurgeon who needs such an elementary treatise on diagnosis, and yet it is clearly not intended for anyone else

Lehrbuch der Röntgendiagnostik (5th ed Stuttgart Thieme 1950 Parts 1 and 2 Pp 426, 452 D.M 66 70)—Before the war this textbook in German, by H R Schinz and others, had a wide international circulation It consisted of two fairly large volumes compiled by radiologists in Switzerland, Germany Austria, Italy, and Scandinavia During the war, the whole of the standing type was destroyed by bombing, and a number of the contributors died, so that the editors have had to start from scratch The new edition, in 6 parts will appear in 3 volumes This first volume deals with the physics of radiation methods of production of X rays, and crystallography and with normal and abnormal radiological appearances of the skeleton An average of 1½ illustrations appear to a page, and the pages measure 11 × 8 in The introductory section on the physics of radiation is unnecessary, being too advanced for the average radiologist, it might prevent him from exploring the good things to come Every conceivable variation is described in detail and liberally illustrated with beautiful drawings and radiographs, there are 90 sketches of fractures of the humerus alone Part 2 describes avascular necroses, inflammations and hereditary disorders, with the same detail The main emphasis throughout is on anatomical and pathological changes as compared with the X ray findings Clinical findings are not adequately correlated, but this is otherwise a superb work The printing, the quality of paper, and the illustrations excel the best pre war German standards

Dental Ancillaries

FACED with the breakdown of the school dental service, and armed with an unexpectedly unanimous and favourable report[1] on the use of school dental nurses in New Zealand, our Government may well be inclined to create an ancillary body of dental nurses in this country But the visiting mission agreed that the New Zealand system might need modification before it would be suitable here As the dental and medical professions will be directly concerned with any such scheme, they should be ready to consider critically and constructively whatever version may be officially proposed

Here in England we have so far had little experience of the work of dental ancillaries During the war the Royal Air Force trained a few " oral hygienists to clean and scale teeth and 20 of these are now working for local authorities or in hospitals Civilian training courses, lasting a year, began at the Eastman Dental Hospital in November, 1949, since when 30 students have been enrolled , and a subcommittee of the standing dental advisory committee of the Central Health Services Council is watching this experiment The work of the New Zealand dental nurse, however, differs from that of the English oral hygienist both in scope and in responsibility The New Zealand nurse receives two years intensive training and becomes something of a specialist in minor dental operations for children, such as filling and simple extractions certainly she is more experienced in this work than most recently qualified dental surgeons On the other hand, so that she shall not feel frustrated in the day-to day routine of children s dentistry, or feel that she has acquired knowledge she cannot use, her training is limited and practical and no attempt is made to stimulate a scientific attitude of mind Nevertheless when she has finished her training and is posted to a clinic in one of the six administrative districts into which New Zealand is divided, she becomes virtually an independent dental practitioner The principal dental officer who is responsible for the dental nurses of his area has about 80 of them in his charge, and cannot closely supervise their work In practice he seldom visits each clinic more than once in a school term, and a good deal of responsibility is thus placed on a nurse who has been deliberately trained as an ancillary worker Many dentists who might otherwise approve of having a similar scheme for this country regard this degree of supervision as inadequate But this is not an objection in principle to using nurses in children's dentistry, and it could be overcome by different administrative arrangements For instance, if a qualified dentist were at the head of a team of 6 dental nurses, the situation would be very different , for their supervision would then be as close as that of students during their training in conservative dentistry in dental schools The dental surgeon in charge of the team would examine patients, and allocate each child to one of his nurses for treatment, reserving for himself the more complex and difficult cases He would probably give all injections for block anæsthesia, and he might have time for orthodontic treatment

Many dentists are now deterred from entering the school dental service because so much of children s dentistry consists in repetitive routine Many are also discouraged by a sense of helplessness in face of this colossal problem Freed from much of the routine work by the ancillaries in his team, the dental surgeon, as MACGREGOR[2] lately suggested, could give time to the specialty for which he has been trained, and in so doing need no longer blame himself for neglecting the urgent attack upon dental caries In the United Kingdom at present there are probably nearly 5 million children needing some form of continuous dental treatment In New Zealand each nurse looks after 500 children , but fortunately the incidence of caries is somewhat less in Britain, and a nurse here ought to be able to look after at least 750 On this basis we should need about 6000 nurses to build up a satisfactory service There are at present about 825 school dental officers, and with their number raised to about 1000 they could undertake the administration of the scheme and the supervision of its ancillary members To organise and equip a children's dental team would be relatively straightforward in towns and also in those country districts where children can go to central clinics In sparsely populated districts, where mobile units would be needed, the organisation would no doubt have to be more rudimentary , but it should be possible to provide each team with one fully equipped mobile surgery, for the use of the dental surgeon in charge, and folding chairs, foot engines, and portable cabinets of instruments for the dental nurses When visiting an outlying village, the team might take over the village hall or transform the schoolroom into a temporary clinic, for a day or two of intensive treatment Though perhaps not entirely satisfactory, such arrangements would be infinitely preferable to the absence of dental treatment of any kind

The recruitment of so many dental nurses will not be easy nor can it be done quickly The training will be costly, and as LITTLEFIELD[3] has pointed out, so long as facilities for training are limited, we must ponder how far it is wise to train dental nurses at the expense of fully qualified dentists Because of these difficulties even a modified ancillary service will be a long-term remedy But unless the dental profession accepts and uses a great deal of help, most of the children of the country can never hope for any but emergency dental treatment Dentistry will remain a " breakdown service ' destined to go on providing dentures for most of the population indefinitely

Analgesics Compared

THE drugs used to relieve pain are of two main classes—narcotics, such as morphine, its derivatives, and the newer synthetic compounds like pethidine and amidone , and antipyretic analgesics, which include aspirin, phenacetin, acetanilide, phenazone, and amidopyrine In general, only a narcotic will relieve the severest pains—from a major fracture, myocardial infarction, renal or biliary colic, or inoperable malignant disease Whereas aspirin and others of its class are often effective in other types of pain, such as headache, and especially so in "rheumatic" conditions of the muscles, fasciæ, or ligaments , their action is said to be potentiated by small amounts of codeine (as in tab codein co) but accurate information on this point is scanty

Among the narcotics morphine is still supreme, for none of its substitutes, whether built from the morphine molecule (diamorphine, codeine, dilaudid, and metapon) or synthesised on a different pattern (pethidine and amidone), has overcome its disadvantages and retained its efficacy Pethidine is less liable than morphine to cause nausea and vomiting or constipation, and it is also the least depressant of the narcotics to respiration , hence its extensive use in obstetrics where avoidance of neonatal asphyxia is vital But it is clearly a drug of addiction, and the same applies to other piperidine compounds, such as bemidone and particularly ketobemidone [1] Amidone ('Physeptone,' 'Methadon,' or '10820') is much more powerful an analgesic than pethidine and even a little more potent than morphine, but it is almost as depressant to respiration as morphine and often causes nausea and vomiting if given by mouth It has hardly any of morphine's sedative action, which is a disadvantage before operations but a valuable feature for patients who want to be relieved from chronic pain while retaining their mental clarity It must be regarded as a drug of addiction, though withdrawal symptoms are slower to develop and less severe than with morphine In small doses amidone effectively relieves useless coughing, and it is widely prescribed in linctus form for children with whooping-cough The need for special precautions in prescribing pleasant tasting syrups containing such potent drugs is well illustrated in the case reported by Dr Roxburgh and Dr Munro Faure in their letter on p 174 Here a girl of 4$^{1}/_{2}$ years with whooping cough was prescribed a proprietary linctus containing 2 mg of physeptone, and gr $^{1}/_{12}$ of phenobarbitone in each fluid drachm A safe amount for her to take would have been not more than 2 4 mg of physeptone four hourly But in fact, because her coughing continued, she was given 12 drachms, containing 24 mg of physeptone and gr 1 of phenobarbitone, over six hours After a day's coma and two further days of somnolence the child recovered The makers of the linctus (Messrs Burroughs Wellcome & Co), in a circular letter, say there have been 3 fatal cases of this kind , they therefore advise doctors prescribing for children to order not more than 2 fl ounces of the linctus, suitably diluted, at a time and to impress on the parents or other attendants that the dose on the bottle must in no circumstances be exceeded Phenadoxone ('Heptalgin') belongs to the same chemical group as amidone and has much the same analgesic action, though of briefer duration

In all the modifications of the morphine molecule hitherto investigated analgesic potency runs roughly parallel with habit formation Thus diamorphine (heroin) is the most powerful and codeine the weakest in both respects The same tendency is seen in the newer synthetic compounds In 1946 Grewe[2] synthesised a new compound, containing 4 of the 5 cyclic rings present in morphine, and a derivative of this, 3 hydroxy-N methylmorphinan hydrobromide ('Dromoran'), is a more powerful analgesic than morphine [3] , but once again it is now regarded as a potential drug of addiction [4] One begins to wonder whether it is basically impossible to dissociate the morphine like capacity to relieve pain from the liability to cause addiction Hardy and his colleagues[5] suggested that morphine relieves pain in three ways

(1) By raising the pain threshold and interfering with pain perception

(2) By detaching pain perception from the usual reaction pattern to pain , though still perceived and recognised as such, pain now seems to be a remote happening which occasions no anxiety This effect resembles that of leucotomy—it might even be said that morphine produces a reversible "pharmacological leucotomy"

3 By inducing lethargy and sleep

The second mechanism appears to be the most important in relieving pain, and since this state of detachment may be very pleasant (euphoria) it is not surprising that predisposed people readily become morphine addicts But does it necessarily follow that no centrally acting analgesic can possibly relieve severe pain without inducing euphoria and causing addiction ? At any rate, no such drug is yet known.

The antipyretic analgesics act quite differently from the narcotics Presumably their antipyretic effect in feverish conditions is brought about through the temperature regulating centre in the hypothalamus heat loss being increased by sweating and cutaneous vasodilatation Their analgesic action is more difficult to explain [6] They are usually said to depress the pain centre, but if so they must act at a different site, or by a different mechanism, from the narcotics, since they do not produce euphoria or addiction Furthermore, morphine can be shown to increase the strength of any stimulus required to elicit pain, but it is very difficult to demonstrate that aspirin has any such action on the pain threshold Sonnenschein and Ivy [7] have found that aspirin (as well as amidopyrine, acetanilide, and phenacetin) has no greater effect than lactose on the pain threshold of a tooth stimulated by an alternating current or the skin stimulated by radiant heat Coburn [8] drew attention to the action of salicylates in reducing joint effusions in rheumatic fever , Meyer and Ragan [9] suggested that gentisic acid, a metabolic product formed in the body from salicylates, may inhibit inflammatory processes and so relieve pain , Barbour and Hermann [10] showed hat these drugs alter fluid and electrolyte balance so s to cause hydræmia, SONNENSCHEIN and IVY herefore suggest that the antipyretic analgesics relieve ain through their local actions on the pathological rocesses causing pain All that can yet be said is hat this possibility deserves further study

Biochemistry of Old Age

THE next major advance in human biology, comparable to the last half century's work on nutrition, endocrinology, and infectious diseases, may well be the elucidation of the mechanisms of ageing This is a field where even the groundwork has yet to be done Between the fatalists who regard any attack on ageing as "against Nature" and, at the other extreme, the rejuvenation fanatics with their exaggerated claims, until lately no attempt has been made to find out what senescence is and what are its primary and subsidiary causes One important discovery in this field could easily activate a whole new train of research The immediate tasks for the biologist are descriptive and experimental, the geriatrician has plenty to do in applying existing medicine to old people and in remedying by exposure the disgraceful conditions under which some of them live From the social side, much has already been achieved by the survey work of SHELDON[1] at Wolverhampton and THOMSON[2] in Birmingham The theoretical background is still confused and confusing It has long been suspected that the factors which limit somatic growth also play a part in the induction of ageing, and McKAY's[3] experimental study of growth-delay and longevity in rats fully supported this view Useful results may come from Russian work being done at Kiev on the relation of ageing to the reticulo endothelial system Now that the Notre Dame laboratory has succeeded in raising germ free mammals, it should be possible to dispose experimentally and for good and all of the bacterial toxic theory The endocrine approach, after being seriously discredited by over optimism, looks far more hopeful now that it is generally agreed that no single hormone or organ is likely to provide a complete explanation of age processes as a whole

In Birmingham an investigation now in progress is based on ALBRIGHT's concept of a human "adreno pause"—a steadily diminishing production of adreno cortical hormones starting at various ages between 60 and 90 The idea draws support from the known decline in urinary excretion of 17-ketosteroids after the age of 50 Preliminary results published by MARSON[4] show that, among 100 women over 60 the axillary hair was absent in 40 and reduced to under fifty hairs per axilla in 87 Potassium and chloride serum levels were normal, but half of the 57 serum-sodium estimations done were significantly low, and the range was 296–340 mg per 100 ml, compared with the normal 320–350 mg Insulin sensitivity was in general reduced, and both the fall and recovery of the blood-sugar levels were sluggish by comparison with younger adults The series is too small for the findings to be more than pointers, but they confirm ALBRIGHT's own figures and support the general hypothesis of a cessation or reduction in adrenal activity The low levels of serum-sodium with no corresponding fall in chlorides, if the findings are confirmed, may throw new light on tissue dehydration in old age The sodium levels again fit in with the view that the adrenal is involved in the age process The rôle of the pituitary is not yet so clear ACTH is a powerful inhibitor of protein synthesis, and MAYER[5] has pointed out that senescence is characteristically a "reorientation of metabolism towards nitrogen equilibrium and fat synthesis" FINDLEY[6] has suggested that decreased tissue sensitivity to pituitary stimulation is a factor in ageing, which would make the process largely peripheral PARKHON[7] has studied the effect of thyroid on the fat-nitrogen ratio in senescence and experimental thyroidectomy Thyroid function certainly declines with age, both clinically and as judged by I^{131} uptake,[8] and much work has lately been done on the relation between thyroid activity and atheroma, by way of the blood level of cholesterol

The vast mass of publications on sex hormone effects in ageing is confusing and largely unreliable, but some tangible relation between œstrogens, androgens, and metabolic processes in senescence have emerged It seems certain that old age is a general failure of homœostasis, though the origin of the process, and the possibility of attacking it at any one point, remain in doubt But the term "adrenopause" is doubly unfortunate, for it suggests a landmark akin to the true menopause, rather than a gradual decline, and by emphasising the adrenal at the expense of other hormonal degenerative changes it begs a question which should at all costs be kept open Little real progress is likely until some essential experiments on tissue biology are done which show exactly how and where the internal environment and the response of cells to it vary with age What is needed is an extension of the brilliant work of the chemical embryologists to cover the end as well as the beginning of the growth process This may tell us what chances there are of delaying or otherwise modifying the degenerative changes of old age

The Displaced Registrars

THE continuing concern over the position of registrars threatened with dismissal, and of the hospitals that are to be denied their help, is reflected in a letter to an M.P from the Secretary of State for Scotland (see p 164) and in a memorandum by the Fellowship for Freedom in Medicine (summarised on p 178) In the first report of the Newcastle upon Tyne Regional Hospital Board, Dr W G Patterson, the senior administrative medical officer, suggests that senior registrar posts should be tenable, on an improved salary scale, for 6–7 years, with a promotion barrier half way through this period, and that full consultant status should normally not be reached before the age of 35 and until twelve years after qualification Whatever its merits in the present crisis, as a persisting feature of our hospital organisation such a scheme would have the defect of leaving the doctor until his middle thirties in ignorance of whether he was to gain a permanent hospital post Hence we prefer the idea of establishing junior consultant posts, carrying the title of specialist, as discussed in our issue of Dec 9

Annotations

CHOICE OF CAUSES IN HODGKIN'S DISEASE

THE histological picture of Hodgkin's disease in the lymph glands and other organs is more like an infectious granuloma than a neoplasm, and there have therefore been many attempts to find the infective agent Ewing was dramatising a fairly common observation when he remarked that tuberculosis follows Hodgkin's disease like a shadow, but the evidence that Hodgkin's disease is either an atypical reaction to *Myco tuberculosis* infection or a manifestation of avian tuberculosis does not carry conviction, nor do the claims to have implicated diphtheroid or brucella organisms In 1932 Gordon[1] demonstrated, in an extensive research, that when material from lymph gland tissue in Hodgkin's disease was inoculated intracerebrally into rabbits they developed an encephalitic reaction leading to paralysis, ataxia, and sometimes death Later, in these columns,[2] he identified the encephalitogenic agent as a virus and even demonstrated elementary bodies in affected cells Unfortunately subsequent work showed that intra cerebral injections of some normal tissues, such as bone marrow and spleen, can produce the same reaction in rabbits, and eventually it became clear that the responsible agent, whether obtained from healthy tissue or from the lymph glands in Hodgkin's disease, is derived from the eosinophil cells[3]

The virus theory has lately been revived in Sweden, where Lofgren and Lundbäck[4] have isolated a virus from ground lymph glands or pleural exudate in 2 out of 6 cases of Hodgkin's disease They have also cultivated it from 1 of their 2 cases of lymphosarcoma, though only after the gland material had been stored at − 70°C for five weeks Material from the negative cases was taken through 5 allantoic and 5 amniotic passages without result After 3–5 egg passages the agent developed agglutinins for the red cells of several animals, and it was shown to fix complement in the presence of serum from 2 out of 5 patients with Hodgkin's disease This work, which follows their demonstration of a closely similar agent in sarcoidosis,[5] is still experimental and clearly requires further investigation

A different approach has been explored by Gendel and colleagues,[6] who had noted an apparent association between Hodgkin's disease and cryptococcosis, or torulosis, a systemic infection with the fungus known as *Crypto coccus neoformans, Torula histolytica, Debaryomyces neoformans, Cry meningitidis*, &c [7] The infection most commonly attacks the central nervous system, though *in many cases* the lungs and skin are also involved Gendel et al have collected 163 published cases and add 2 of their own, 14 of these 165 cases (8 5%) were associated with Hodgkin's disease—a proportion unlikely to occur by chance In 13 of the 14 cases Hodgkin's disease was diagnosed before cryptococcosis In the 14th case, one of the new cases reported by Gendel et al, both diagnoses were made at necropsy This patient had had Hodgkin's disease for about four years and X ray treatment for about a year He developed bilateral pleural effusion and ascites, with chylous fluid He did not respond to nitrogen mustard treatment and began to complain of headache, and the cerebrospinal fluid yielded a growth of *Cry neoformans* The patient died, and post mortem studies revealed cryptococcal infection in the pleural but not the peritoneal fluid, the organisms were also demonstrated in areas of cystic degeneration in the lungs, periaortic lymph glands, spleen, brain, and elsewhere The normal structure of the periaortic glands was replaced by pleomorphic tumour cells and hyalinised fibrosis, a picture distinct from the Hodgkin's disease areas, similar tumour-like cells were found at other sites The most likely explanation is that Hodgkin's disease weakens the patient's resistance to infection and allows the cryptococcus to win a foothold and spread But it is also possible that the fungus can produce a histological picture simulating Hodgkin's disease or one of the other reticuloses This would support the view that Hodgkin's disease is a response to infection by a variety of micro organisms

BIRTHMARKS AND MOLES

ANGIOMATOUS nævi (birthmarks) and pigmented soft nævi (moles) are by far the commonest congenital defect of the skin Dilatations of blood and lymphatic vessels sometimes also affect the subcutis, muscles, and bone, causing enlargement of part or the whole of a limb Rational treatment of these anomalies depends on a knowledge of their natural history, and this subject was discussed at a meeting of the section of surgery at the Royal Society of Medicine on Jan 3, when Mr D N Matthews described the following clinical types spider nævus, neonatal staining, superficial capillary hæmangioma, port wine stain, cavernous (mixed) hæmangioma, arterial hæmangioma, diffuse hæmangiomatous giantism, and multiple familial telangiectasis, in which lesions may also occur in internal organs and in the mucous membranes, causing epistaxis, hæmoptysis, or hæmatemesis

The spider or stellate nævus is simply dealt with by diathermy, the galvanocautery, or electrolysis to its central vessel and any conspicuous branches Neonatal staining clears up on its own As for the others, the port wine stain is usually a lifetime possession, because unlike the superficial capillary hæmangioma or strawberry mark, it is not associated with proliferation of the endothelial cells but only with a static dilatation of the vessels in the corium Its treatment consists either in excision and plastic repair, or in cosmetic coverage Before deciding on surgery it is well to attempt the latter, because cosmetic technique today has reached a stage where even dark purplish stains can be rendered much less noticeable, while even after operation cosmetic assistance may still be necessary to conceal scars

Three ways in which hæmangiomata may enlarge were mentioned by Mr Matthews they may grow by budding of new endothelial tissue, by canalisation of existing vasoformative tissue, or by tapping an additional blood supply from neighbouring blood vessels The third method may lead to very rapid growth Upward growth may lead to ulceration, which may be followed by fibrosis and slow healing, but often with a ring of residual hæmangioma Growth downwards may in some cases lead to erosion of vital organs, such as the eye Hæmorrhage following ulceration may be a serious complication with hæmangiomata mainly composed of arterial or cavernous tissue, whereas with capillary hæmangiomata it is not a serious matter Mr Matthews believes that spontaneous shrinkage of hæmangiomata is uncommon compared with extension—a view with which many would disagree Fading without treatment may occur by thrombosis and infarction, or by infection, fibrosis, and strangulation Mr Matthews said that excised hæmangiomata may show no sign of fibrosis, and he thought this made it improbable that they often clear on their own He did not, however, discuss their possible disappearance

[7] In recommending *Cryptococcus neoformans* the Medical Mycology Committee of the Medical Research Council remark that they do so without prejudice to any change of name becoming necessary later (M R C memo no 23 London, 1949 p 6

By natural processes which are not yet understood t seems significant that whereas the scars of surgical procedures and irradiation for nævi are commonly observed in later childhood and in adult life, one very rarely sees a strawberry mark nævus after the age of five years This suggests that spontaneous disappearance is common, for only a small proportion are excised W A Lister[1] followed up many cases of this sort and noted rapid growth during the first year or so, followed by a static phase, after which the great majority began to fade and disappeared without trace before the end of the fifth year A useful routine scheme is to measure the lesion accurately at the first attendance, or photograph it beside a rule The mother is advised of the probable subsequent progress, disabused about folk lore and the gratuitous advice of the woman next door regarding "male and female nævi," and asked to bring the child for periodical inspection If at about eight or nine months the lesion seems to have stopped growing, it can be safely left to run its natural course Surgical interference is necessary chiefly in the cavernous type, for hæmorrhage, rapid extension, and deep erosion and in cases with severe disfigurement or involving the mouth, ears, or orbital or perianal regions—sites at which rapid extension and disfigurement, or interference with functions, such as deglutition, may occur

Mr Matthews described surgical treatment by the use of sclerosing agents, or excision, or a combination of the two methods Sclerosing agents are effective particularly in the cavernous (mixed) type, in which this form of treatment most often becomes necessary Suitable methods include heat, cold, irradiation, and the injection of sclerosing solutions Diathermy is preferred to cautery Carbon dioxide snow is used by many, but may leave a disfiguring ring of angioma around the scarred area Mr Matthews strongly deprecated the use of γ irradiation for these benign lesions of childhood—an opinion which should receive wide support Sir Stanford Cade, who presided at the R S M meeting, spoke of possible stunting of limb growth from its use and said that if it was applied to the mammary region in young girls it might lead to non development of the breast at puberty with the ugly scarring of atrophic radiodermatitis, the result might resemble that of a complete mastectomy with subsequent irradiation The treatment of port wine stains by γ irradiation is also contraindicated, but α irradiation by thorium X paint containing 1500 electrostatic units per cubic centimetre, applied at fortnightly intervals, has been recommended as safe, and is sometimes followed by improvement in cases of nævus flammeus, where the individual vessels are not too obvious before treatment is begun Sclerosing fluids include boiling water, 40% saline solution, and 'Ethamolin' froth These, Mr Matthews said, may cure or may lessen the extent of surgery afterwards necessary The best results are obtained by first applying transparent adhesive tape under pressure over the lesion and then injecting through this Mr D F E Nash recommended the use of an all metal dental syringe with a fine flexible needle for easier and safer injection procedures

Turning to moles, Mr Matthews recommended excision in toto and grafting if necessary sometimes only partial excision is possible and in these circumstances a central plaque graft, subsequently stretched, gives the best results He did not deal, however, with the vexed question of the relationship of moles and malignancy The removal of moles about the face is usually requested for cosmetic reasons, and apart from removal of the hairs by electrolysis, their simple excision gives most satisfactory results Some believe that any handling of these lesions may initiate malignant changes, but histological findings suggest that this is unlikely, for the nævus cells are of the intradermal (resting) type Confusion has arisen with junction (active) nævi in which the nævus cells are situated at the junction of the epidermis and the dermis These are usually hairless, more intensely pigmented, and bluish black, and the patient may come for treatment not for cosmetic reasons but because the lesion has lately been enlarging or bleeding In cases of this sort careless manipulation, or even a biopsy, may lead to the grim results which have placed something of a hoodoo on the treatment of moles Nevertheless it is a wise precaution not to subject *any* mole to forceps pressure during its removal, and to refer all moles for histological study Moreover, they should be widely and deeply excised Probably all pigmented moles on the hands or feet or in the axillæ or groins, ought to be excised as a prophylactic measure, because of the risks of trauma at these sites Malignant melanomata tend to arise in the parts of the body more distant from the head, and lesions on the soles and in the paronychial regions are especially suspect, even if pigmentation is inconspicuous or absent

CLASSIFICATION OF CANCER OF THE CERVIX

The classification of cancer of the cervix uteri adopted by a League of Nations committee and published in 1937 was enthusiastically adopted by many countries and marked a big advance in the presentation of results of radiotherapy in this form of cancer Indeed it gave a lead which might well be followed by all doctors seeking to evaluate the results of treatment of their patients

The committee's aim was to provide a classification that would be accepted everywhere, so as to secure a common basis of understanding and comparison of the results obtained by radiotherapy centres throughout the world In the United States, however, this classification of carcinoma of cervix into four well defined stages has not been used exclusively, and at the fourth American Congress of Obstetrics and Gynæcology, held last year, an international committee was appointed to find a classification that would be acceptable to all centres treating cancer of cervix This new committee has now recommended that the League of Nations classification of carcinoma of cervix should in all essentials be retained, with the one exception that cases of carcinoma in situ should henceforth be removed from stage I and placed in a new category, stage O As thus revised, the stages will be

> *Stage O* —Carcinoma in situ—also known as pre invasive carcinoma intra-epithelial carcinoma, and similar conditions
>
> *Stage I* —The carcinoma is strictly confined to the cervix
>
> *Stage II* —The carcinoma extends beyond the cervix, but has not reached the pelvic wall The carcinoma involves the vagina, but not the lower third
>
> *Stage III* —The carcinoma has reached the pelvic wall (On rectal examination no "cancer free" space is found between the tumour and the pelvic wall) The carcinoma involves the lower third of the vagina
>
> *Stage IV* —The carcinoma involves the bladder or the rectum, or both, or has extended beyond the limits previously described

The committee resolved that "this Classification should be termed the International Classification of the Stages of Carcinoma of the Uterine Cervix, and that all organisations concerned with the problem on hand be approached to consider its adoption "

With the introduction of stage O, pre invasive or intra-epithelial carcinoma of cervix—the so called carcinoma in situ—is placed in a stage by itself Technically, pre invasive carcinoma is within stage I, but its prognosis is not the same, the growth being still confined within the basement membrane and therefore likely to be much more amenable to treatment. The usefulness of this modification in staging will largely depend on the acceptance by pathologists and other specialists of a diagnosis of cancer based on the cytological study of the cervical epithelium. This is a method of diagnosis that enjoys much popularity in America, where cancer-detection centres are widely established and great numbers of examinations by the smear technique are made in laboratories with trained staff concentrating on this study. The position in many other countries, however, is different, and this method of diagnosing cancer has so far been less generally accepted outside the U.S.A. If, with greater experience, the method becomes a routine procedure for all patients undergoing gynæcological examination, a welcome advance, not only in earlier diagnosis but also in the results of treatment, should follow. For this reason in itself, apart from the clearer basis for comparison of results of treatment offered by the addition of a stage 0, the new classification deserves adoption.

PROSPECTS IN THE TUBERCULOSIS SERVICE

PULMONARY tuberculosis still needs—and doubtless gets—more beds and more outpatient hours than any other disease; even so, it does not get enough of either. Dr G. E. Godber, deputy chief medical officer of the Ministry of Health, remarked at a conference of the public health section of the Royal College of Nursing, on Jan. 13, that we *cannot be satisfied with conditions which do not enable us to treat the early case, or isolate the infectious case, at once*. These, indeed, are the prime necessities in the public health management of any infectious disease; but the difficulties of achieving them for tuberculosis are of course formidable. Lack of money is possibly the chief of them, but lack of nursing staff for beds, and lack of houses also tell against the tuberculous. Probably nothing tells so heavily, however, as the awkwardness of human nature. Dr Godber admitted, cautiously, that he did not feel sure that the chest physicians and the medical officers of health were everywhere working well together; and other speakers must have encouraged his doubts. *There is much to be said* for his view that the preventive aspect of tuberculosis has rightly been left in the hands of the local authorities, since the M.O.H. has our preventive machinery constantly in use under his hand. The health visitor, being primarily a dealer in prevention, has been left on his staff. But this division of responsibility is certainly giving rise to trouble in some places. Dr Philip Ellman, who took the chair, felt strongly that the health visitor must be present when the patient is attending the clinic; but in some areas she is not allowed to attend sessions at the chest clinic or is not able to attend all sessions. She thus loses an important chance to understand the cases and keep continuous touch with them, while the chest physician loses a valuable lieutenant. A nurse sent in from the local hospital—perhaps a different nurse each week—cannot give him the same informed help as the health visitor, who knows the patient's home.

That this kind of friction is quite unnecessary was made clear by speakers from regions where collaboration between the health department and the chest clinic is good. At Southend, Dr E. G. Sita Lumsden said, the M.O.H., the assistant M.O.H. (who is also the school medical officer), the superintendent health visitor, the home help supervisor, the superintendent of nursing, the chief sanitary inspector, the children's officer, and the chest physician all meet weekly to discuss the cases of tuberculosis under treatment and to arrange what each shall contribute to their care. This plan works well. The committee so formed are in touch with the housing authority and advise about patients who need rehousing, taking care to propose only those for whom a change is really necessary. Dr Sita Lumsden has also encouraged the general practitioners to send all suspected cases and contacts to the clinic for X-ray examination; and this has favoured early diagnosis to such an extent that a mass radiography survey detected only a very small number of new cases. Such an example of successful collaboration may be contrasted with the experience of a sanatorium physician who said that while they had found it possible, in her area, to form good relations with the thoracic surgeons and general practitioners, they had not succeeded in interesting the medical officer of health—or indeed the entire local authority. The sanatorium of 220 beds has no almoner. Many lung resections are done there, and it has been her experience that patients who before admission had high priority for housing, after lung resection—when their need of good quarters is often very high—are taken off the priority list. This sanatorium, which employs reabled nurses, is never short of staff, and indeed sometimes has a surplus; *but there is no room for more beds in the existing building*. Yet there is a long list of patients awaiting admission in the region.

Dr Marc Daniels reminded the *meeting* that the allocation of beds for tuberculosis in general hospitals is the one thing which can act immediately on waiting lists. Here again progress depends on good feeling. In some places, he said, there is considerable opposition from regional hospital boards and hospital management committees. Domiciliary treatment can be successful only if the chest physician can use hospital beds for short-term measures of treatment; but these measures can be used only if they are supplemented by a good clinic service, and some of the clinics are quite inadequate. Dr Godber mentioned a recent Ministry of Health survey, unfortunately still confidential, which has shown that "a surprisingly large number" of chest physicians now have hospital beds at their disposal—news whose value must depend on the surprise threshold of the Ministry.

A question about the pool of infection in London's common lodging houses brought Dr William Hartston to his feet in defence of the London County Council. What goes on in Rowton Houses, he implied, is not the council's affair: the 200 cases in common lodging houses, which the L.C.C. inspects, represent no more, he thinks, than the incidence in the general population. At three of the best houses (where every man has his own cubicle and can cough to his own satisfaction) the L.C.C. has arranged that cases recommended by a chest physician should have priority of admission; and that they should be allowed to lie down on their beds in the afternoons. A hostel has been opened in the country for homeless tuberculous patients who are not fit for work, and another is to be opened in London in March for working men. This is not much, but it is something. Only money—a great deal of money—can put everything right; and at the moment we cannot afford so much. That is all the more reason for pressing forward with measures which cost nothing but good will—the allocation of beds in general hospitals, and a closer collaboration between the chest physician and the M.O.H. Whatever happens, Dr Godber believes we should never again allow the tuberculosis service to work in isolation, out of the stream of general medicine. It offers plenty of work for everyone concerned—the chest physician, the M.O.H., the general practitioner, the health visitor—if they will agree to share it.

Dr J. EASTMAN SHEEHAN, professor of plastic reparative surgery at New York Polyclinic Medical School, has died in New York. During the late war he worked in London for some time and he contributed to our columns papers on skin grafting and on facial paralysis.

THE ADRENOCORTICOTROPIC HORMONE (ACTH) OF THE PITUITARY GLAND

C J O R Morris
Ph D Lond , F R I C
READER IN CHEMICAL PATHOLOGY IN THE UNIVERSITY OF LONDON
From the endocrine and medical units, the London Hospital

THE intimate connection between the pituitary gland and the adrenal cortex was first satisfactorily demonstrated by Philip Smith in 1928–30 Using his newly developed technique of hypophysectomy in the rat, he showed that the removal of the pituitary caused a relatively rapid atrophy of the adrenal cortex, which could be repaired by transplants of anterior pituitary tissue The active principle was later called pituitary adrenocorticotropic hormone (ACTH) Shortly after Smith's work H M Evans (1933) showed that pituitary extracts could also bring about adrenal repair in the hypophysectomised rat

CHEMISTRY

Many attempts were then made to isolate the hormone , but little real progress was made until the rapid development in protein chemistry produced the modern techniques for separating and characterising proteins

In 1943, Li, Evans, and Simpson, at Berkeley, California, working with sheep pituitaries, and Sayers, White, and Long, at Yale, using pig pituitaries, independently isolated proteins with high adrenocorticotropic potencies These preparations, which were very similar in chemical and physical properties, seemed to be homogeneous in sedimentation, electrophoresis, and solubility studies Their molecular weight was 20,000

The preparation of a protein of similar biological potency from beef glands has been cited by White (1944), but no physicochemical data have been published, and efforts in the London Hospital laboratory, and in that of Dr C H Li (personal communication), to isolate a homogeneous beef ACTH preparation have so far been unsuccessful

The amounts of ACTH present in the pituitary glands of different animals vary widely Astwood and Tyslowitz (1942) showed that pig glands contained most, sheep glands rather less, and beef glands least ACTH Sayers et al (1949) estimated that the human pituitary may contain ACTH equivalent to 20% of the dry weight The yields of homogeneous protein hormone obtained from animal glands have been lower than these estimates would suggest Fishman (1947), by a modification of the earlier methods, obtained 1 g of homogeneous protein hormone from 1 kg of pig pituitaries (about 5000) Li et al (1943) originally obtained 60 mg from 1 kg of sheep pituitaries, but Li has obtained much higher yields from these glands by a modified procedure

Though the evidence for the homogeneity of sheep and pig protein ACTH preparations appears to be satisfactory, there is now much evidence that the active principle may be of relatively small molecular size Li et al (1943) reported that about 60% of the protein could be digested with pepsin without loss of biological potency Li (1947) showed that a similar effect was observed after partial hydrolysis with hydrochloric acid, and from a study of the digestion products he concluded that the active fragment is a polypeptide with a molecular weight of about 1200

Evidence of another type comes from ultrafiltration experiments Anselmino et al (1934) and Tyslowitz (1943) claimed ultrafiltration of A.C.T.H. activity through membranes impermeable to protein, but neither was able to prepare the hormone in more concentrated form Work at the London Hospital began in 1938 (Crooke et al 1947) Cortis Jones et al (1950) have shown that by ultrafiltration of beef ACTH concentrates under suitable conditions it is possible to prepare a mixture of polypeptides which is 1 5–2 0 times as active as homogeneous pig ACTH and contains about half the biological activity initially present in pituitary glands A polypeptide (ACTP) isolated from this mixture seems to be homogeneous and is ten times as active as homogeneous pig ACTH (Morris and Morris 1950) It thus seems certain that, unlike that of most protein hormones, the biological activity of the adrenocorticotropic protein resides in a small molecular grouping Experiments in the London Hospital laboratory suggest that the beef and pig protein hormone molecule is made up of a group of peptides held together by relatively weak forces This complex can be dissociated and reassociated by changes of pH and salt concentration The variation in biological activity in ACTH from different sources, and also the fact that certain heterogeneous protein preparations are more active than the homogeneous protein ACTH, can be explained on this basis The active peptide seems to have all the different biological properties associated with the protein hormone

The implications of the idea of a relatively small active grouping are very important for our understanding of the action of ACTH Since the space occupied by this group at its site of action is about the same as that occupied by many synthetic drugs, such concepts as that of competitive inhibition, which have played an important part in modern pharmacology, may also be relevant here Work in this direction must of course await the elucidation of the amino acid sequence in the active grouping and the determination of the chemical specificity of the biological action

Lesh et al (1950) have recently announced the preparation of material having 120 times the potency of Armour standard from pig pituitaries This material had a molecular weight greater than 2500 and contained at least twelve different amino acids If this preliminary report is confirmed, the concept of ACTH as a component of the protein hormone of Li et al. (1943) and Sayers et al (1943) must be abandoned

BIO ASSAY

Valid assays of ACTH can be made only on hypophysectomised animals in which the endogenous source of the hormone has been removed Many erroneous reports of the presence of ACTH in blood and urine have been made through neglect of this principle Three main methods are now generally used for bio assay of the hormone

(1) *Adrenal Repair* —Hypophysectomised rats are kept for 10–14 days after operation The adrenals then weigh 25–30% of those of controls The material to be tested is administered in divided doses and adrenal repair estimated by increase in adrenal weight or by histological examination

(2) *Adrenal Maintenance* —Administration of the material to be tested is begun *immediately after* hypophysectomy, and the amount of test material necessary to maintain the adrenals at the normal level is estimated

(3) *Adrenal Ascorbic acid Depletion* —Sayers et al (1945) observed that injection of A C T.H leads to depletion of adrenal cholesterol and ascorbic acid, and that this depletion coincides with the liberation of glucogenic hormones from the adrenal cortex They suggested that these are synthesised from cholesterol in the adrenal cortex by some process involving ascorbic acid Sayers et al (1948) have used the depletion of adrenal ascorbic acid by ACTH in the hypophysectomised rat as a sensitive and specific bio-assay method for the hormone As little as 0 5 µg of pig A.C.T.H., or 0 05 µg of beef A.C.T.P., produces a 20% depletion This method is probably the best now available

PHYSIOLOGY

The various biological effects produced by ACTH are mediated *solely through the adrenal cortex* In laboratory animals adrenalectomy abolishes all these effects, and in many cases they have also been duplicated with pure adrenocortical steroids The chief physiological actions of the hormone are

Production of Adrenal Hypertrophy

It has been stated that the adrenals of the rat can be increased in weight from about 30 to 400 mg by continuous intravenous infusion of ACTH Bergner and Deane (1948) show that in the rat this hypertrophy is confined mainly to the zona glomerulosa, but the existence of a species difference does not warrant the extension of this conclusion to man

Synthesis of Adrenocortical Hormones in the Adrenal Glands

As mentioned above, injection of ACTH causes depletion of adrenal ascorbic acid and adrenal cholesterol Sayers et al (1943) showed that this process was accompanied by the increased deposition of liver glycogen typical of the action of adrenal glucocorticoids ("S hormones") The characteristic decrease in the number of circulating eosinophils brought about by these substances has also been demonstrated in man, mouse, and rat after administration of ACTH Estimations of "11-oxysteroids" (which give a rough indication of the excretion of glucosteroids) in patients receiving ACTH also confirm these conclusions Since the administration of ACTH causes an increase in 17-ketosteroid excretion in man, it has been concluded that the hormone also stimulates production of "N" (nitrogen-retaining) hormones by the adrenals, contrary to the earlier suggestion of Fuller Albright (1947) that these substances were controlled by the pituitary luteinising hormone However, certain glucocorticosteroids can give rise to urinary 17-ketosteroids, and as the direct effect of ACTH on the nitrogen balance in man seems to be variable, the question of production and control of "N" hormone must await further investigation Most workers now agree that administration of ACTH in man is followed by marked retention of $Na^+ + Cl^-$, similar to that produced by deoxycortone It may therefore be concluded that the adrenal mineralocorticoids ("Na" hormones) are also under pituitary control in man This conclusion, however, is not valid for mouse and rat

It will therefore be seen that all the known types of adrenocortical hormones can be produced by the adrenal glands under the action of ACTH, and that the over all effects of this hormone will depend on the ratio of the various corticoids produced by the stimulation

Sayers and Sayers (1947) have shown that this mechanism is self regulating injection of certain corticoids—e g, 'Cortisone'—inhibits production of ACTH by the pituitary They have also shown by the adrenal ascorbic acid depletion method that a state of stress elicits increased production of ACTH by the pituitary, and that this effect can be inhibited by injection of corticoids This relation is quantitative, in that a severe stress necessitates a large dose of corticoids to inhibit production of ACTH The glucocorticoids —e g, cortisone and 17 hydroxy corticosterone (Kendall's compound F)—are much more effective in this inhibition mechanism than are the mineralocorticoids Sayers and Sayers conclude that the pituitary secretes ACTH at a rate which is adjusted to the corticoid requirements of the peripheral tissue cells The operation of this mechanism has been reviewed by Sayers (1948)

The physiological effects produced by ACTH, indirectly via the adrenocortical hormones can be summarised as

Inhibition of Protein Synthesis

ACTH inhibits the action of the pituitary growth hormone which regulates the rate of protein synthesis in the organism with a consequent increase in the amount of amino acids in the blood and increased excretion of nitrogen

Increase in Rate of Gluconeogenesis

The carbon chains derived from fats and amino acids are used in the synthesis of carbohydrates This process is mediated by the glucocorticoids, which also increase the storage of glycogen in the liver In rats on a high-carbohydrate diet, or with insulin-deficiency induced by alloxan, ACTH can induce glycosuria Similar effects have been observed in persons with abnormal sugar tolerance curves

Involution of the Thymus Gland and Lymph nodes

Dougherty and White (1945) have shown that involution of these tissues follows administration of ACTH in the normal but not in the adrenalectomised animal They have also shown that there is a corresponding fall in the lymphocyte-count Forsham et al (1948) found a striking depletion of the circulating eosinophils after the injection of ACTH This effect can also be produced by the glucocorticoids, 17-hydroxy corticosterone (compound F), and cortisone (compound E) Forsham et al have suggested a test for adrenal function based on this response The extent of the depletion following administration of a standard dose of ACTH may be regarded as a measure of the amount of functional adrenocortical tissue When adrenal function is impaired—e g, in addisonians—the administration of ACTH produces little or no change in the eosinophil count

Dougherty and White (1945) stated that the titre of certain antibodies in the blood rose after the administration of ACTH and suggested that these were liberated as a result of a breakdown of lymphocytes In view of later negative findings, however, this work requires further corroboration

Changes in Electrolyte Balance

These changes, mediated by the mineralocorticoids, may be summarised as retention of sodium and chloride and excretion of potassium, calcium, and phosphate The latter changes may perhaps be correlated with the retardation in chondrogenesis and osteogenesis in the rat tibia and in the decrease in plasma alkaline phosphatase following administration of ACTH (Li et al 1948). The effects of ACTH on calcium and phosphate metabolism in man, however, require confirmation owing to contamination of preparations used with posterior pituitary hormones

ACTH IN BLOOD AND URINE

Several claims have been made for the detection of ACTH in normal human blood and urine None of these, however, are convincing, because of the bio assay methods used

Taylor et al (1949) were unable to demonstrate ACTH in normal blood by the sensitive and specific ascorbic acid depletion method of assay They were, however, able to detect the hormone in the blood of patients with adrenal deficiency We have recently recovered about 2 5% of the amount administered from the urine of a nephrotic receiving peptide ACTH, and 5% has been recovered from the urine of a rheumatoid arthritic

Greenspon et al (1950) have shown that ACTH injected intravenously in the rat disappears completely from the blood stream in about 20 minutes, with a half life of 5 minutes It thus seems very unlikely that appreciable quantities of the hormone persist in normal blood The need for multiple divided dosage in ACTH treatment is also emphasised by this work

CLINICAL ASPECTS

The preparation of pig protein ACTH on a relatively large scale by the Armour Company in Chicago has made it possible to study the effects of the hormone in man in both normal and pathological states

The results of such studies have in general confirmed the above mentioned work on laboratory animals—with the notable exception of the effect on mineral metabolism As already mentioned, it is clear that in man, unlike the rat, considerable retention of sodium and chloride follows administration of ACTH The original studies of J S L Browne, Fuller Albright, Mason, Li, and Evans and their co workers are collected in the Proceedings of he Josiah Macy Conference in 1948 on Metabolic Aspects f Convalescence (Reifenstein 1949)

The most striking clinical application of A C T H has undoubtedly been provided by Hench et al. (1949a and b), who have shown that it produces dramatic remissions in otherwise intractable rheumatoid arthritis The details of this work, which has been completely confirmed, are now so well known that little further discussion is needed It may perhaps be pointed out that no striking abnormalities of pituitary or adrenal function are known in rheumatoid arthritis and that, as the doses used are far above the physiological levels, the defect in such cases may be in impaired utilisation of the glucocorticoids by the peripheral tissue cells However, Sommerville et al (1950) have shown that the conversion of progesterone into pregnanediol is greater in the rheumatoid arthritic than in the normal person Since deoxycortone is also converted into pregnanediol in man, this observation suggests that abnormal steroid metabolism may also be a factor in rheumatoid arthritis It must be emphasised that the sequence from administration of A C T H to relief of arthritic symptoms must involve many biochemical processes, one or more of which may be defective in rheumatoid arthritis Such considerations may explain the conflicting findings in combined administration of deoxycortone and ascorbic acid It must not be assumed that the essential biochemical defect is the same in all cases

The results produced by A.C T H in rheumatoid arthritis have led to an examination of its effects in many diseases, which can be grouped into three main classes the so-called collagen diseases, the allergic diseases, and the lymphatic diseases

Collagen Diseases

In rheumatic fever A C T H produces effects as striking as those in rheumatoid arthritis The hormone seems to suppress the symptoms and in many instances shortens the course and severity It also seems to alleviate acute endocarditis and pericarditis Diets very low in salt are advisable during treatment of patients with acute cardiac involvement, so as to reduce retention of water Reports on this condition have been published by Hench et al (1949b) and by Massell and Warren (1949) Striking results in disseminated lupus erythematosus have been claimed by Elkinton et al. (1949) and Grace and Combes (1949) A C T.H promptly alleviates symptoms but there is an equally rapid relapse when it is discontinued.

Periarteritis nodosa has been studied by Shick et al (1950) The effects are similar to those observed in other diseases of this group—i.e , relief of symptoms, with recurrence of the condition when A C.T H treatment is stopped

In this connection it is interesting that the skin and vascular reactions produced in rats by injection of horse serum have been shown by Berthrong et al. (1950) to be inhibited by A C T H Rich (1946 47) believes that these vascular changes are identical with those in periarteritis nodosa

Other diseases of this group where a temporary alleviation is produced by A C T.H are scleroderma, dermatomyositis, and psoriasis, but only a few cases have been studied

Allergic Diseases

A C T H. exerts a well marked effect on bronchial asthma and allergic rhinitis (Rose 1949) It was previously known that during acute asthmatic attacks the patient excretes histamine and histidine in the urine During protracted A C T H treatment these substances are still intermittently excreted, but no bronchial symptoms are observed. The circulating eosinophils, which disappear from the circulation on A C T H treatment, have a relatively high histamine content

Lymphatic Diseases

These have been studied by Rawson and his colleagues A very remarkable effect on acute juvenile leukæmia has been observed. Even in extremely ill patients A C T H relieves the symptoms promptly and the blood picture is restored almost to normal within fourteen days but, when A C T H treatment is discontinued, a relapse to the original state occurs Less dramatic changes have been observed in chronic lymphatic leukæmia, acute and chronic myeloblastic leukæmia, lymphosarcoma, and Hodgkin's disease (Pearson et al 1949)

Gout

Injection of A.C T H during a quiescent period of gout induces an attack of gouty arthritis, but injection during an acute attack immediately alleviates the attack (Hellman 1949) The mechanism of the process is not understood but it seems to have no connection with the elimination of uric acid produced even in normal persons by A C T H

Myasthenia

Torda and Wolff (1949) studied cases of myasthenia gravis during A.C T H treatment They observed a partial remission in so far as the patients could reduce the daily level of neostigmine necessary for reasonable activity They also observed improved muscular activity and decrease of the specific cholinesterase inhibitor usually present in the serum of patients with myasthenia gravis The improvement was maintained in one case up to a year after the end of treatment

It will be seen that, in almost all the conditions studied, A.C T H may produce a more or less striking suppression of symptoms but does not seem to alter the essential course of the condition or to affect the fundamental cause

Ophthalmological Disorders

Gordon and McLean (1950) and Olson et al (1950) have studied the effect of A C T H in a number of ophthalmological disorders Amelioration of inflammation was observed in several of them, and these workers believe that A C T.H will be of value in such cases because the improvement seems to be maintained after the end of treatment, in contrast to the other conditions described previously

Virus Diseases and Carcinoma

A C T H seems to have no effect in virus diseases —e g , poliomyelitis (Coriell et al 1950)—or in various forms of carcinoma

The somewhat optimistic hopes which the prompt relief of symptoms in many conditions aroused thus have very little basis A promising line for future work would be to treat the causal factors by other methods while the symptoms are controlled by A C T H

However, the fact that the symptoms of many otherwise intractable conditions have been shown to be reversible is of great importance, and it is evident that A C T H is a physiological tool of great potency, capable of producing fundamental changes in metabolic processes

THE REGISTRARS' CUT

SCOTTISH MINISTER'S EXPLANATION

WRITING to Lady Tweedsmuir, M P, Mr Hector McNeil, the Secretary of State for Scotland, says that he and his officers have been much concerned about the proposed reduction in the number of medical registrars in Scotland, " and I am anxious to persuade you and the public in general as well as the registrars that we have been handling the subject most carefully, without haste, and justly " He continues

" Now I should want to make it emphatically clear at the outset that the changes contemplated are not dictated as an economy measure and that, further, I am concerned, at least as much as anyone else, to see that the standard of medical services in the hospitals is maintained and not impaired by these changes

" It has been apparent for some considerable time that there were far too many registrars under training in hospitals in relation to the number of specialist posts likely to be available in the foreseeable future Now, plainly it was unfair that these young men and women should be left to entertain quite unjustifiable expectations of a specialist career So as long ago as December, 1949, an assessment of the situation by the Department of Health was sent to regional boards for their consideration It was also quite deliberately published in the medical press [1] and elsewhere So I hope that you will agree that we have not acted precipitately and that everyone concerned has had fair and timeous warning of the situation and all its implications

" Further, in June, 1950, a more detailed examination of the numbers in the registrar grades and the optimum number required to meet the needs of the National Health Service for specialists was published [2] and again sent to the regional boards

" The broad conclusion of these studies, i e, that the number of registrar posts would have to be reduced if the training establishment were to be brought into balance, has been generally accepted by the medical profession and the regional boards Consequently, a few weeks ago the Department issued a memorandum to boards specifically asking them to put in hand the necessary adjustments in the hospital staffs so that the number of registrars is reasonably related to specialist prospects in general and, in particular, to the prospective needs for the several types of specialists

" The main cause of the present difficulties is that although the registrar grade was intended to be for doctors training to be specialists it has been used far beyond this purpose and large numbers of registrars are at present unfortunately being employed without any clear idea whether they will be needed later as specialists or whether they are needed now for hospital work which is above the level of a house-officer but below that of a consultant Indeed, there are further irrationalities Although this is exceptional and not at all general, some are being employed in posts (both in teaching and non teaching hospitals) which do not really afford training at all and are virtually a dead-end I hope that you will agree that such situations have to be remedied.

" The Department's memorandum to regional boards attempts to make provision for the maximum number of registrars who can be trained with a reasonable expectation that they will be, if they make the grade, ultimately employed as specialists From the medical staffing point of view it provides in addition for the recruitment of ' clinical assistants who should be able to take over some of the work now being done by registrars and at the same time engage in general practice It also, I should make clear, permits boards to make a case for any other additional posts that they think may be necessary to maintain the essential services of the hospitals.

" I must also mention the question of the level of teaching in our medical schools which must not of course be impaired by these changes As you will know, it is the existing practice for some of the doctors who are training to be specialists to be employed to a limited extent during their training on duties connected with clinical teaching How far it is necessary to provide additional registrar posts in the hospital service because of this will be for each regional board to work out in consultation with the university concerned [3]

" We must, I think bear in mind that at present the medical schools can produce only an approximately fixed number of doctors each year This output has to cover all branches of medicine and of course a regular supply of men and women must be made available for the general practitioner service which, it must be admitted, is the backbone of the whole service I am afraid, therefore, that while we shall of course endeavour to see that the specialist service is developed where necessary, we cannot look to that service to provide unlimited opportunities for the registrars

' Naturally, we have had very much in mind the effect of this policy on the existing registrars and I am personally much disturbed that some of them are bound to be disappointed However, even if their expectations suffer, there are several points which I think they might reasonably expect to bear in mind (1) The recent memorandum from the Department is not a bolt from the blue For more than a year it has been manifest to everyone taking an intelligent interest in the subject that the number of registrars proper would have to be reduced (2) Long before the inception of the National Health Service it was customary that the training for specialist status should be highly competitive and the weeding out process consequently was severe What has happened recently is that the increase in the number of trainees has risen in an excessive disproportion even to the increased number of specialist posts provided by the National Health Service (3) Doctors, like all of us cannot always expect to find posts which give them exactly the kind of career they would prefer Individual preferences must be related to the needs of society and this to some extent must always determine the particular branch of medicine which doctors are to follow Even now there are some specialties in which the opportunities are better than in others and in which so far, there has not been heavy competition for appointments I might mention psychiatry and radiotherapy where there has been some difficulty recently in filling some of the senior posts (4) There is no escaping the fact that many of those registrars now in posts will find sooner or later that there is not a specialist post for them either generally or in their chosen specialty It is, I think, in their own interest that this situation should be faced frankly now (5) We have also to consider the position of the younger doctors now approaching registrar status. It is important that we should preserve for the abler doctors of each medical generation a fair chance to train for the higher posts To bar them simply because of their age in favour of senior men who may not be of the same promise would be unfair both to these individuals and to patients and sufferers whom they would eventually treat

"I am sure that regional boards, who recognise the needs f the specialist service in their areas and know the personal osition of individual registrars, will make the necessary eductions not only with full consideration for the needs of the ervice but seeking also, as far as it is possible, to mitigate ardship for the doctors involved It is perhaps relevant hat I should say to you (without criticism of the excellent nd arduous work overtaken in the other areas) that the uthorities in the North Eastern Region, both before and ince the inception of the new service, have exercised such a legree of caution and restraint in this subject that the lifficulties there are much less severe than those in other arts of the country That the hospitals in the North East iave continued their work at a high standard with a relatively small number of registrars is worth the closest study"

Reconstruction

THE PRESENT STATE OF THE HOSPITALS

FROM A CORRESPONDENT

WITH a colleague, I have been visiting hospitals in several regions What follows is an attempt to summarise our impressions

Let me say at once that, from the standpoint of some of the more progressive hospital management committees (H M C), the new set-up is a success Anyone who visits a series of group headquarters as we have done, will find himself approving the outright unification of the hospital services and the broad plan of local administration by bodies constituted solely for this purpose, combined with a wider regional control of the higher flights of medical affairs The British genius for government by committee, backed by the old sentiment towards the hospitals, has proved its capacity to fuse into a new entity the diverse elements that go to make up the H.M C Continually we were told "the committee is working well, there have been teething troubles, there are still many differences of opinion but it is all right" There is a general, and strong, sense of responsibility for the welfare of the hospital services of the area *as a whole* This is a new thing in hospital affairs, and its emergence is a great achievement, the credit for which can be widely shared The revolution that is actually taking place in the hospital services of Great Britain is placing this country ahead of anything that is happening on the Continent or in the United States

In many groups there is clear recognition of the partnership between the administration on the one hand, and the medical and nursing authorities on the other, in the conduct of hospital affairs Diagrams are produced showing variants on the pattern

HOSPITAL MANAGEMENT COMMITTEE

GROUP MEDICAL ADVISORY COMMITTEE (representatives of each of the hospitals in the group and of each of the specialties)	Subcommittees of H.M C (finance general purposes building &c)	MATRON S ADVISORY PANEL (matrons of all the hospitals in the group)

Such a system may, it is true, often throw a heavy load on the chief officer and his staff, for they may have to attend five or six main committees or subcommittees in the month, often meeting in the evening, not to speak of numerous minor subcommittees Some are more successful in delegating it than others, but even where the load is heavy there can be felt a sense of something achieved, clearly traceable to the fundamentally sound pattern that has been laid down Practice with regard to house committees varies In some groups they have been abolished, as a hindrance to "group mindedness" In others they have become in effect, and sometimes in name, welfare committees, controlling the amenity funds of the hospitals and sometimes minor staff appointments

SOME BENEFITS

The reorganisation has resulted in, or greatly accelerated, many tangible benefits to the patients Apart from the spread of consultant services—on which more is said below—many examples have been quoted to us of improvements on the old arrangements Hospitals of any size which do not employ a catering officer and maintain a tolerably good standard of feeding are becoming rare—though of course there is still much to be done in this field A new conscience has developed over arrangements for admission and in regard to medical records, prompted and greatly assisted by the King's Fund publication of 1948 In almost every hospital one is shown how the authorities are grappling with the ancient tradition that it does not matter how the patient is received provided he or she somehow hobbles into the ward The large old outpatient waiting halls have given way to more or less successful systems of appointments for outpatients The old institutional brown or green dado of passages and corridors is being replaced by cream and light pastel shades, over which a great deal of trouble is plainly being taken Many of the wards in out of the way places—even those in war time huts and other converted buildings—reach a standard of friendly comfort which can challenge comparison with the leading hospitals in cities All this is being done despite the discouraging heritage of buildings dating back to the poor law of a hundred years ago, and sometimes including the workhouses of earlier days still These latter are often empty their former inmates have been moved to homes for the elderly In fact hospital administration is well and truly on the move

The spread of consultant and specialist services from the larger centres over other units has been the responsibility of the regional boards Working out an establishment for each area and granting contracts on a whole time or sessional basis—the latter has so far been by far the most popular with the consultants—has been a protracted process, and the resulting pattern is only now becoming apparent

The H M C must have been glad to be passive partners in these somewhat personal proceedings, sometimes, it seems, contracts have been granted and payment begun although there were not yet facilities for the necessary beds or clinics

Often the new plan has meant development of consultant staffing which leaves no room for the former medical superintendent of the local authority hospitals Many superintendents have been glad to avail themselves of the opportunity to become consultants and to resign their administrative functions, but in other cases agitated discussion is still going on It seems to be agreed that in many such hospitals there do remain some semi administrative semi medical functions which can best be performed by a medical superintendent, probably under some different title In one case the former medical superintendent of a large local authority unit spoke enthusiastically of the advantages of the present set up, remarking upon the fact that he felt that he was now in closer touch with his committee than under the old county régime Where there are cottage hospitals the general practitioners are naturally apprehensive lest the coming of the consultant services will mean that they are eventually squeezed out, and it is difficult to get a clear picture of exactly what is happening The consultants are being called on increasingly for domiciliary visits, for which they receive fees under the National Health Service additional to their sessional remuneration Though occasionally abused, these visits are of great value, and many patients who would never have seen a consultant in former times if they could not go to the hospital are to that degree better served today

MEDICAL ADVISORY COMMITTEES

Group medical advisory committees (G M A C) are now an established institution in all groups we visited, and relations with the H M C appeared to be almost uniformly good The medical men on the H M C itself do seem to act, as of course they should, as representatives of the G M A C Sometimes the secretary of the group acts also as secretary to the G M A C, and this seems to have worked well in nearly all cases where it has been given a fair trial It provides an important link between the H M C and its medical staff, now that the staff is largely appointed regionally, and functions in hospitals which are geographically far from group headquarters, it can easily happen that the members of the H M C and their lay officers do not even know by sight the medical staff of their own hospitals

NURSES

While medical staffing is mainly a matter for the regions, the responsibility for nursing rests squarely upon the H M C itself Numbers are going up, and though there is still a shortage there is a good deal of confidence among the authorities Two main trends may be discerned First, efforts are being made to develop existing (or establish new) general nurse training schools in the most important secondary hospital centres in the group It seems to be not uncommon to find the old training school at the former voluntary hospital still blessed with ample student nurses, and stress being laid on upgrading one or more of the larger ex local authority units to constitute a second—perhaps numerically larger—general training school Such schools seem to have a fair prospect of recruiting enough staff, because of the increase of surgical and other acute work being undertaken in their wards But there is also a movement for the establishment of "assistant nurse" training schools, under the revised General Nursing Council regulations, to take care of the miscellaneous units—chiefly chronic sick—which are still excluded from the purview of the hospitals with the general training schools There is, as yet, no sufficient body of experience to tell us whether these assistant nurse training schools are likely to be a success or whether it would have been better to allocate all the beds in the group among the general training schools

This is a matter on which the new General Nursing Council will need to keep its ear close to the ground A wrong decision might compromise the new hospital service at this its weakest spot It would be a tragedy if once again the upgrading of some were achieved at the cost of downgrading of others

Two factors were frequently mentioned which tend to make the nursing situation more difficult than it need otherwise be First, the long standing social distinction between different hospitals Though social distinctions are beginning to disappear and members of the medical staff are, here and there, sending their own families to what were formerly poor law hospitals, the feeling is still strong among the nurses Second, the poor quality of much of the accommodation is a sad handicap Some of it is so incurably "institutional" as to defy all modernisation Large houses are being bought to supplement the accommodation—often in beautiful surroundings but somewhat distant from the hospitals Comment may also be made upon the state of the sanitary annexes in many of the hospitals It is now generally agreed that modern bedpan sluices are a distinct asset from the point of view of the nurse, but they are by no means universal Often they are said to be "in the programme," but this is said without much conviction as to when they will materialise This seems mistaken policy at a time when availability of nursing care is, in every group we visited, the final decisive factor in developing the service

DIFFICULTIES

Are there any serious snags ? It is encouraging to be able to say, so far as the hospitals are concerned, No (The impact of all this on general practice is another matter) With the obvious exception of the need for large scale capital development, which now seems to be deferred indefinitely, there are no really important snags Impatience with regional boards for delays and lack of comprehension of local conditions is much less evident than it was a year or so ago

The provision that "savings" must be returned to the Exchequer is regarded by all intelligent H M C personnel with whom we spoke as sheer folly [1] There is surprisingly little anxiety about the restriction of maintenance expenditure to present levels most H M C s seem to feel that with care they can manage pretty well Attention is focused rather on minor capital items, which have little chance of going through in present circumstances An example would be the extension of a staff dining room which would save half its capital cost in a single year by permitting reduction in staff There seems to be no evidence of regional officers visiting and going into such matters with the thoroughness which alone would justify taking this kind of thing out of the hands of the local committee the contrary is the case In one instance we heard of representatives of the H M C having been given "ten minutes" before a subcommittee of the regional hospital board to press the claims of its extensive capital programme Some extension of management committee powers to cover minor capital items—perhaps if they could be met out of "savings" ?—would go some way to relieve such tension as does exist between H M C and the regional authorities An alternative—or possibly supplementary—remedy would be to permit or indeed to encourage the use of "free" monies for these purposes In some areas free money is piling up, and there is indecision as to whether it may be used in support of projects which could theoretically be met from Exchequer funds

The lack of an accessible summary of hospital statistics is felt acutely to quote from the observations of one finance officer appended to an elaborate set of financial statistics covering an expenditure of a million pounds a year—"No information is available at present which would enable me to say how these percentages compare with other groups, but it is hoped that the board will one day find it possible to meet this need and thus afford some guidance to the committee on the matter"

The regions have not—so far—published their programmes of capital developments, and the management committees lack information about the general plan They do not know why the claims of other hospitals are placed before their own, or what steps the regional board is taking to press on the Ministry, and on public opinion generally, the need for a more liberal attitude to capital expenditure upon the hospital services [2] Some few items are given a "first priority," but these are apt to be the larger projects and it seems that many minor but nevertheless highly desirable improvements may never succeed in getting to the front of the queue

H M C AND ADMINISTRATION

Our visits made us aware of the immense importance of the right approach to the administrative work in the H M C In the H M C the administrators are being thrown into positions of great responsibility covering the whole of the hospital services of wide and populous areas, with budgets in some cases running at a million pounds a year and equal in size to those of the largest teaching hospitals. The men have been kept on their toes; they have to struggle with the problems of introducing consultant staffing among hospitals primarily staffed by general practitioners, and with finding nurses and other staff for large and somewhat intractable blocks of chronic sick, tuberculous, and other patients. Obviously some have been more successful than others but it is encouraging to find, so soon after the revolutionary changes of 1948, numerous examples of real progress and solid achievement.

S W Metropolitan 1951–52 £1 000 000 1952–53 £1 200 000

Public Health

RESULTS OF SANATORIUM TREATMENT IN THE MIDDLE-AGED AND ELDERLY

M. B. PAUL
M.A., M.D. Camb.
LATELY ASSISTANT MEDICAL OFFICER, LIVERPOOL SANATORIUM, FRODSHAM

THE present shortage of sanatorium beds makes it imperative to use them to the best advantage. As things stand, many patients seem to derive very little benefit from their stay in a sanatorium.

The bad prognostic significance of a persistently positive sputum was demonstrated by Thompson (1942), who found that of 406 patients with positive sputum 42% died within twelve months of diagnosis, and only 1 in 8 survived ten years. Sputum-conversion is in fact the most important single objective of treatment. Unfortunately, however, the collapse therapy which is so useful for this purpose is seldom applicable to patients in the older age groups, and the prospects of obtaining sputum-conversion are thus considerably reduced as age increases. The only treatment for most of these patients is routine sanatorium care, with the main emphasis on rest and graduated exercise—measures designed to increase general resistance to the disease. Such treatment seems to be of doubtful value unless indefinitely prolonged, and the question arises whether the results at present obtained justify the use of beds for this type of case.

CLINICAL MATERIAL

This paper is based on 107 consecutive admissions to the Liverpool Sanatorium since Jan. 1, 1946, of patients aged 45 and upwards whose stay in the sanatorium has ended.

Of these 107, 86 were men and 21 women, these figures roughly corresponding to the higher incidence of the disease in men in these age groups found by Hebbert (1948). The age range was 45–70 years, and the duration of treatment 5–375 days, with an average of 124. The type and extent of disease as shown by radiography was as follows:

In 68 cases there was bilateral tuberculosis with cavitation; in the majority the disease seemed to be predominantly fibrocaseous, while in a few the appearances were of softer more recent disease. In 20 cases the disease was unilateral though in some the lung was extensively affected. Carcinoma of the bronchus was diagnosed in 2 cases, upper lobe bronchiectasis in 8, and inactive tuberculosis in 8. In the remaining case the X-ray film was normal though the sputum was said to have been positive before admission.

Tubercle bacilli were found in the sputum in 64 cases; in 30 the sputum was negative, and 2 patients had no sputum. In the remaining 11 cases the sputum was persistently negative while the patients were in the sanatorium, but tubercle bacilli had been found shortly before admission. Most of the cases of tuberculosis were classified as moderately advanced, but 14 were far advanced on admission. A few had coexisting disease which further worsened the prognosis: 2 had diabetes mellitus, 3 had severe basal emphysema, 1 had silicosis, and 1 had tuberculous pericarditis.

TREATMENT

In this series it was seldom possible to apply measures designed to control the local lesion; conservative treatment with the object of improving the general condition was the most that could be given. Nevertheless, artificial pneumothorax treatment was tried in 19 cases.

In 12 of these it was either impossible to induce a pneumothorax, or the pneumothorax was abandoned—either at once, as being contra-elective, or later after an effusion had formed. One patient died after a coronary thrombosis while undergoing artificial pneumothorax treatment. In the remaining 7 the artificial pneumothorax was maintained; 4 of these cases were thoracoscoped and 2 had adhesions divided. In 1 case in order to control a 'dorsal' lobe cavity, the pneumothorax was supplemented by pneumoperitoneum. This was the only case in which sputum conversion was obtained, the criterion demanded being three consecutive negative smears and one negative culture.

The majority of the remaining cases in the series were given short periods of bed rest of one to two months and were then allowed up on hours in graduated stages. A few did not improve sufficiently to be allowed up, and these remained in bed until death or transfer elsewhere. A few cases that showed a good response to the preliminary period of bed rest were given more prolonged rest up to six or nine months. The cases of doubtful activity were allowed up at once and intensive sputum tests were carried out meanwhile.

One case of bronchiectasis of the left upper lobe was treated by lobectomy. One patient, whose X-ray film showed soft infiltration in the middle and lower zones of the left lung and whose sputum was positive before admission, was given a ten weeks' course of streptomycin and *p*-aminosalicylic acid with almost complete clearing of the infiltration.

RESULTS

Of the 107 patients, 22 discharged themselves, 9 died, 2 were discharged for infringement of the rules, and the remaining 74 completed the prescribed course of treatment. The results, assessed according to clinical condition, are as follows:

Clinical condition	*Cases*
Unchanged	40
Slight improvement	39
Considerable improvement	14
Worse	5
Died	9

These results are based on objective findings such as gain in weight, diminution in quantity of sputum, lowering of the erythrocyte sedimentation rate (E.S.R.), temperature, and pulse-rate, and on the subjective findings of a reduction of lassitude and feeling of ill health, and a reduction in cough and dyspnœa.

Judged by changes in the radiological appearance, the results were:

Radiological appearance	*Cases*
Improved	21
Worse	11
Unchanged	55

The cases classed as improved showed a clearing of infiltration or a diminution in cavitation or both. Only 87 cases are included, because the other 20 cases were not radiographed again, owing to death or premature discharge.

Assessment of the results on the incidence of sputum-conversion shows that this was achieved in only 1 case—in the patient treated by artificial pneumothorax supplemented by pneumoperitoneum. In a few cases, however, intermittent negative smears were obtained where previously all had been positive, and it is possible that the degree of infectivity of some cases was temporarily reduced

DISCUSSION

These results show very clearly how little the individual patient unsuitable for active treatment benefits from sanatorium treatment It can, of course, be fairly argued that only half—or even quarter—measures have been applied in most of these cases, for none of them had really lengthy treatment such as was prescribed in the earlier days of sanatorium treatment Today, however, *in this age of shortages and of priorities, it does not* seem reasonable to give prolonged treatment to such patients when it means further delay in the admission and treatment of cases more amenable to therapy

If we cannot expect to materially alter the prognosis for these patients, is it logical to admit them to sanatoria at all? The answer to this question depends largely on the temperament and clinical condition of the particular patient, and it behoves the chest physician to assess each patient carefully from all angles before recommending him for sanatorium treatment The large number in this series who took their own discharge shows that many older patients are unable to adapt themselves to the discipline of a sanatorium, and the main desire of many of them seems to be to get back to their familiar haunts and habits—especially when no active treatment is given A secondary objective of sanatorium treatment is the education of the patient in precautionary measures, and in the nature of the disease and the need to lead a regular disciplined life with a correct balance between rest and exercise This objective is seldom attained with older patients, for they are slow to learn and practise precautions The two patients discharged for infringing the rules were both observed spitting in the grounds

Another reason for admitting this type of case to a sanatorium is to prevent the infection of Mantoux-negative contacts at home Actually it is usually found that all susceptible contacts have been infected by the time the diagnosis is made, but there will always be some cases in which protection of contacts is a major consideration This object is defeated if the patient is discharged infectious in some cases, indeed, the result of treatment has been to convert a bedridden infectious case into an ambulant one, thus increasing the risk to the community in general In a few cases beds will have to be provided for seriously ill patients who cannot be nursed at home, but from the point of view of convenience and expense to the relatives in visiting, it is better that such beds should be in a tuberculosis ward in a general hospital

In several cases in this series no evidence of active disease was found The decision as to whether or not an abnormal X ray appearance is due to active disease should be made at the chest clinic and not at the sanatorium, since all necessary investigations—such as gastric lavage, laryngeal swabbing, estimation of E S R, tomography, bronchography, and bronchoscopy—can be performed on outpatients The resources of the sanatorium should be used in treating those cases which are amenable to active treatment

Wynn Williams et al (1950) have given details of a scheme which successfully reduced a sanatorium waiting-list This has the great merit of realism, but it calls for much cooperation between chest physician and sanatorium superintendent Under this scheme, patients who—because of advanced disease, or age, or for other reasons—are considered unsuitable for collapse therapy are not, except in special circumstances, admitted to a sanatorium, instead, they are kept at home under the careful supervision of the chest physician and health visitor This frees many sanatorium beds Tattersall (1949) has pointed out that a coöperative patient can be taught by the health visitor many of the precautions which he would learn in a sanatorium as well as a suitable regimen to adopt

The policy of admitting to sanatoria only those cases which are suitable for active treatment will be impracticable unless there is a sufficient nursing staff But it might, by making the work more interesting, improve the recruitment of nurses for sanatoria

SUMMARY

1 The present serious shortage of sanatorium beds demands that every available bed be used to the best advantage

2 The results of sanatorium treatment in a series of 107 middle aged and elderly patients, most of whom were unsuitable for collapse therapy, suggest that the use of sanatorium beds for this type of patient is not justified at the present time

3 Patients of this class should, whenever possible, be treated at home under the supervision of the chest physician and health visitor, and priority for sanatorium beds should be given to patients who would profit from active treatment

Influenza

Statistics for the week ended Jan 6 pointed to an increased incidence of influenza throughout England and Wales The figures for pneumonia cases and deaths and for influenza deaths in the Great Towns during the six weeks up to Jan 6 were

	Week ended					
	Dec 2	*Dec 9*	*Dec 16*	*Dec 23*	*Dec 30*	*Jan. 6*
Pneumonia						
Cases	282	347	374	364	502	956
Deaths	198	236	280	351	383	578
Influenza deaths	28	34	33	54	102	458

Of the 458 deaths from influenza, 339 occurred in the region north of a line roughly from Crewe through Sheffield to the Humber, and these deaths were largely associated with outbreaks on Merseyside and Tyneside Here the disease was generally mild, though highly infectious, and the deaths, with very few exceptions, were among elderly people

There was some increase in deaths from influenza in all regions, including London and the South East, compared with the preceding week However, in the week ended Jan 6 deaths certified as due to influenza in London County numbered only 40 It seems that, particularly in the North and North-West, the disease is becoming somewhat more severe

The numbers of new claims to sickness benefit also indicate an increased prevalence of influenza Whereas in the week ended Dec 19 claims totalled 128,842, in the week ended Jan 2 they totalled 240,223

In the areas in the North and North-West that were originally attacked the epidemic seems to have passed its peak There is, however, evidence of increased prevalence in areas that so far have not been seriously affected The position in the South up to Jan 10 remained uncertain There was, however, serological evidence of virus-A infections, and virus A was isolated from garglings in one case during the week ended Jan 13

Influenza Abroad—Prevalence is high in Belgium, Holland Denmark, and Greenland, and the disease is probably prevalent in Northern Spain. In Holland the virus is apparently virus A very possibly of the A prime type as in the Swedish outbreak, which was the first in Europe this winter

Smallpox at Brighton

Up to noon on Jan 16 there had been 30 cases of smallpox in the Brighton area 8 patients had died

Cases have come mostly from three foci

1 *Bevendean Hospital*—All the initial cases from here were employed in the ward on which the 2nd case was nursed for ten days 8 of the patients belonged to the day or night nursing staffs and 2 were ward maids Of these, 3 nurses and the 2 domestic workers have died During the past few days 4 other cases have occurred in the hospital These were connected, more or less directly, with the personnel on the affected ward

2 *Laundry*—The clothing of the original case was sent here, and from this 6 employees have contracted the disease, 2 laundry workers have died

3 *Telephone Exchange*—The 2nd case was employed here, and 2 further cases have come from this source

In the past week 4 cases have been notified which do not belong to the three main foci, and these patients were not under surveillance when they developed the disease Rather tenuous circumstances may relate these cases to existing foci, but the position is not clear Other cases of this type have to be expected Only now is the infection which was disseminated from the three foci, before strict surveillance was set up, becoming manifest

Although the disease is confined to the Brighton area and there is no sign of spread to other parts of Great Britain, the strictest vigilance is still imperative throughout the country

INCIDENCE OF VACCINATION

In his report for 1949, Dr I Gordon, acting medical officer of health for Ilford, records an investigation of the incidence of vaccination among children attending infant-welfare centres In fifteen centres the incidence varied from 54 to 22%, and Dr Gordon remarks ' It is apparent that children living in the three districts which contain the higher income groups are protected to a greater extent than those living elsewhere in spite of the fact that vaccination is free "

Poliomyelitis

In England and Wales notifications of poliomyelitis during the week ended Jan 6 were paralytic 37 (36), non-paralytic 10 (17), total 47 (53) Figures for the previous week are in parentheses

Notifications in the corresponding week of the previous four years were 1947, 10, 1948, 58, 1949, 20, and 1950, 54 The figures for this week in 1948, 1950, and the present year are comparable to the extent that in each case the incidence of the disease in the previous year was very high

The Third Quarter

In England and Wales during the quarter ended Sept 30, 1950, the infant-mortality rate was the lowest ever recorded for any quarter, the rate, provisionally corrected, was 24 per 1000 related live births This is reported by the Registrar General,[1] who gives the death-rate for the quarter as 9 3 per 1000 population, compared with 9 2 for the corresponding quarter of 1949 Deaths from acute poliomyelitis numbered 373 (provisional total), compared with 264, 330, 86, and 71 in the four preceding quarters

The birth-rate was 15 4 per 1000 population, compared with 16 6 per 1000 for the corresponding quarter of 1949, and an average of 18 0 for the third quarters of the five years 1944–48 Illegitimate births accounted for 4 8% of the total births registered, compared with 5 1% in the corresponding quarter of 1949 The stillbirth rate was 22 3 per 1000 total live and still births—0 3 higher than for the third quarter of 1949

Births exceeded deaths by 67,323, the corresponding increases for the third quarters of 1947, 1948, and 1949 being 119,409, 90,310, and 82,031

In England Now

A Running Commentary by Peripatetic Correspondents

Stephen Potter has not mentioned doctors in his book *Lifemanship*, either because he did not realise what a vast structure of ploys and gambits we work in, or more probably because he was appalled by its immensity Countless generations of doctors, from Hippocrates with his oath to the men of today with their doctor-patient relationship, have built up such a system of Lifemanship that even the most insignificant physician can guarantee to retain the essential " one upness " with 95% of his patients

Fifty years ago the successful doctor was said to need three things a top hat to give him Authority, a paunch to give him Dignity, and piles to give him an Anxious Expression Now top hats are out of fashion, the paunch has been rationed away, and liquid paraffin has relieved the anxious expression, but somehow our Authority has grown stronger while the other two wilted away I should like to see Frith Morteroy, Odoneda, or even Potter himself survive a consultation with his physician and retain his one upness to the end The initial verbal encounter usually demoralises any but the hardiest spirits, though there have been patients who hit back at this stage You may remember the example recorded in these columns, where a mother, no doubt roused to a cold fury by the pædiatrician's persistent and wholly irrelevant interrogation, began to inquire into his own past history Then there was the rather similar case where a patient was being asked by the surgeon how long he took to pass water and was replying in the usual indefinite manner—" Quite a while Some time About three months " and so forth Finally, stung by the surgeon's insistence on what seemed a wholly unreasonable degree of accuracy, he said " If I may ask, Sir, how long do *you* take ? " Lay Lifemen will be disappointed but not surprised to hear that this ploy had no effect on the surgeon, who replied without a second's hesitation, " Two minutes dead "

Patients who have preserved their equanimity through the questioning regarding their bowels and water, their habits with wine and women, and their incomes, now face Ordeal by Examination Here there falls out of the fight the woman whose secondary sex characteristics are derived not from nature but from Bond Street at 10*s* 6*d* a pair, and the elderly young man whose slim waist-line is preserved not by rugger but by a belt, and, of course, those who only wash for appearances' sake and not for hygiene (*Note* A resistant patient can often be shaken by making him remove his socks.) Those gallant few who possess torsos like Greek gods and silk underwear, and therefore have nothing to hide, are now subjected to indelicate exploratory investigations with the index finger which soon reduce them to fundamentals

Finally there are the weapons of Diagnosis and Prognosis, although these must be used with discretion The doctor who gives his patient six months to live is in a weak position when he meets him two years later But when applied carefully a suitable diagnosis and well-balanced prognosis should fittingly terminate an interview in which the professional Lifeman has held all the trumps

* * *

After Mr Noel-Baker's broadcast appeal for fuel economy the group round the registrars' dining table were discussing what our several departments could do The surgical registrar agreed that the theatre was the greediest consumer, with its lighting and heating, the flood of hot water poured into the drains in the ritual of scrubbing up, and the diathermy apparatus " I'll hand the Old Man a scalpel next time he wants a diathermy cautery," he said hopefully, " it ought to incandesce quite enough in his grasp And the new H S gets so hot and bothered when his retractor slips that he should save a lot on heating " " I suppose your department, Psyche, uses the least electricity," drawled the E N T registrar, " you wrap your patients in blankets on a couch and sit behind them in a dimly lit room so you can snooze in comfort In fact you're pretty well always in the dark " " What about E C T though, and electronarcosis ? " asked the others , " they're enough to cause a nation-wide power cut " The medical registrar did not join in the discussion, his mind being permanently occupied by thoughts of his forthcoming encounter with the Preceptors We had to be content with making him promise not to burn the midnight oil

* * *

There is, I fear, no doubt that My Work has become an obsession and is seriously interfering with My Life I find myself refusing invitations to sherry parties because they interfere with My Work, and I dread the telephone bell lest it interrupts me at it I go shooting, of course, on Saturday afternoons, largely from force of habit, but I always refuse to stay to tea afterwards, hurry home, clean my gun, and settle down to My Work. Worst of all, perhaps, My Work has virtually put a stop to My Serious Reading A reluctant half-hour in bed is all I can spare for that What is My Work, you ask ? Well, if you must know, I am making a wool rug and am determined that—unlike so many others—it shall be finished "*Fecit* 1951" is to be worked tastefully in blue in the top right-hand corner, and if all this is not evidence of senescence I should like to know what is

* * *

In Casualty the other day we were haunted all the afternoon and evening by a lady with an unalterable conviction that we were detaining her husband there or elsewhere in the hospital Like an unhappy spectre she searched under couches, behind curtains, and in even more improbable places, not one whit deterred by the assurances of Sister and the casualty officers She made the life of the admission clerk a misery all day by catechising him on the name of every patient in all our many hundred beds , his solemn declaration that we had no man of her name in the hospital was met with a hostile stare of cold disbelief At midnight, when she had been getting in our way for eight or nine hours, scrutinising each new face myopically, her tune changed—the lost spouse had apparently died of waiting, and while mourning his departure she was now seeking her daughter Firmly shown the door in the small hours, she was yet back with the dawn , and finally she had to be persuaded to continue her search on the guiding arm of a stolid Metropolitan constable

* * *

I can sympathise with my peripatetic colleague of Dec 16 (p 821) who has had to learn the Derbyshire usage of English the hard way, because I spent some delightful and enlightening months as an assistant in the Yorkshire coal-field during the war when I had just emerged from the depths of Central Europe, knowing only the English of the Warner Brothers, augmented by some virile but rarely applicable adjectives picked up on service with the Merchant Navy There was that abdominal emergency, announced by an early morning caller with a terse " It's coming both ways with Mrs X," the nature of which became obvious when I reached the bedside of the old lady Thanks to my long Boy-Scout and military experience, plus a lively imagination, I soon grasped the implications of that common complaint in the surgery, " I cannot go to the ground, Doctor "

* * *

My friend who has not long been in partnership with two doctors in Kansas tells me that on Christmas morning he got a present of a case of beautiful apples from a Mr Grimme He told his partners about it, and asked who Mr Grimme was " Mr Grimme," they replied, " why he is the undertaker in the next block " " I see," said my friend " Did you two get apples too ? " They were a little embarrassed by this question " Why, no," they told him, " we got oranges You do better next year and then you'll get oranges too "

Aphorism of the Week

Disseminated sclerosis is the orange peel of orthopædics

Letters to the Editor

PROSPECT OF WAR

SIR,—There is an increasingly widespread assumption, both within the profession and elsewhere, that world war is inevitable Concerned by this defeatist attitude we have met together to exchange ideas and now feel impelled to express ourselves publicly

Five years have passed since the Allies achieved a victory of desolation through unconditional surrender and massed bombing Twenty million men, women, and children were killed or maimed , millions were made to suffer greater indignity and mental and physical torture than the human spirit has ever known, and, of these, many were the noblest characters of their day Now, even the perspective of atom warfare fails to arouse horror , the magnitude of threatened disaster paralyses the mind We shrug the terror away and take comfort in resolute preparations to find hospital beds for the survivors But the evils of war long antedate the outbreak £1,000,000,000 spent in preparation for war (to kill before we are killed) are £1,000,000,000 not spent on houses, schools, hospitals, health centres, and research. Each pound spent on bombs means not only bodies burnt to death in the future but more dead babies now, more families broken by tuberculosis, more jaded women old before their time, more young delinquents Food becomes scarce again , old people barely survive on their pensions

" War is an anachronism " " War never achieves the ends for which it is fought " " There are no warmongers nobody wants war " These are truisms, but every day the news comment in the papers and the speeches of responsible men are putting before us a picture of the world in which it seems that war cannot be avoided These voices name the enemy as communist Russia Sooner or later, they say, Stalin will invade us, and it is useless to negotiate till we are ready to fight him , our motives are clear and innocent, his are clear—however much he may attempt to disguise them—and wholly evil If he offers to meet us, it is only that he may seize the opportunity to make a treacherous attack We are told that communist Russia has enslaved or hypnotised the millions within her borders while our peoples are free , that her government is reckless of human life and that we cherish it

Is this so true a picture that we must acquiesce in the headlong drive to war—a war which must come out of the arms race as inevitably as the depression of human standards follows from the preparation for it ? Is it not likely that the " enemy " is given the same picture, but with hero and villain interchanged ? Willingness to cooperate and to understand the other man's rights and needs are hallmarks of civilisation , belligerency and self interest are not " Negotiation from strength " is as good or as bad an axiom as " The best defence is to attack " Both are the slogans of battle, the equivalent of the schoolboy's " I dare you " Above all else, the great issues of peace and war demand dispassionate judgment , yet thought about them has become charged with irrational emotion

We appeal to all our fellow doctors who think there may yet be an alternative to merely providing treatment for casualties , we ask them to join us, in the spirit of our chosen profession of healing, in doing all in their power to halt preparation for war and to bring about a new and determined approach to the peaceful settlement of disputes and to world disarmament

TROPIC OR TROPHIC

SIR,—It matters very little whether the pituitary hormones are called -tropins or -trophins, the meaning of a word depends on usage and not on etymology and few of us are good classical scholars. The main trouble at the moment is that the terms employed are long and clumsy or else are replaced by a group of capital letters which mean little to the uninitiated. What we need are new short, euphonious, and clear names. I am bold enough to suggest a few, though I am certain that many of your readers can do better.

Growth hormone somatophin.
Adrenocorticotrophic hormone adrenophin.
Follicle stimulating hormone folliculophin.
Luteinising hormone lutophin.
Interstitial cell stimulating hormone leydophin (but how many people are familiar with Leydig's cells).
Thyroid stimulating hormone thyrophin.
Lactogenic hormone lactophin.

VACCINATION AGAINST SMALLPOX

SIR,—Dr Killick Millard's paper last week is of considerable interest to me as the abandonment of infant vaccination in this country was the subject of a discussion at the Yorkshire branch of the Society of Medical Officers of Health last June, and a paper of mine on this subject is now in the press. My arguments, however, are based on the low level of herd immunity attained and not on the grounds that Dr Millard advocates.

Dr Millard's main argument is that mild cases of variola major only occur in the vaccinated. In my opinion this is fundamentally wrong, as all types of smallpox, from fulminating to mild, can occur in the unvaccinated. In a series of cases that I reported from Tripolitania 105 cases of types 6 and 7 (discrete and mild) occurred out of a total of 300 cases in unvaccinated patients. A type 6 case occurred as an intra-uterine infection while the mother had a malignant type 2, neither, of course, having been vaccinated. Dr Millard also minimises the difficulties associated with the diagnosis of the most severe types. Although true hæmorrhagic smallpox, the purpura variolosa of Ricketts's and my classifications, occurs in probably only 1 or 2% of cases, malignant confluent type 2 cases occurred in 73 of this unvaccinated series. As experience in Glasgow has shown, this type of case may be in a general hospital for five days before being diagnosed.

In my experience modification of the virus of variola major does not occur by passage through either unvaccinated or vaccinated persons. Mild cases in unvaccinated or vaccinated persons give rise to all the different types, the proportion depending upon factors in the herd immunity, either inherited or acquired by vaccination. It is impossible to decide the infectivity of severe or mild cases from quoting a few isolated cases. The most bizarre trains of circumstances sometimes occur. There are plenty of examples in the literature of both severe and mild cases being the origin of outbreaks, although the mild case is usually ambulant and, therefore, a considerable danger to the community. The infective period, however, is probably shorter, and experience shows that the maximum risk occurs in close contacts in the family and at work. It should not be forgotten, however, that the malignant case which ultimately dies may be ambulant on the second or third day of the disease, between the pre-eruptive and eruptive phases, and the presence of many lesions in the mouth and larynx increases the weight of droplet infection.

Dr Millard refers vaguely to "a vast amount of vaccination in India" having no appreciable effect on smallpox incidence. When one considers India's population of some 400 million, the difficulties of vaccination, and the relatively short duration of absolute immunity, it is very doubtful if 5% of India's total population are immune at any one time. One would not expect this to have any appreciable effect on incidence, but the fault is not with vaccination. While all would wish that the immunity produced by vaccination was more lasting, I am surprised to see Dr Millard suggest introducing variola minor into India as a remedy. Surely this is likely to confuse patient and medical profession alike.

As we have no carriers of smallpox virus it must not be forgotten that if the world ever reaches a stage of peace the United Nations could for a small sum of money, compared with the cost of armaments, carry out a smallpox eradication scheme for the world, by a once-for-the-last-time vaccination.

MASS RADIOGRAPHY

SIR,—It is not practicable now, or in the foreseeable future, to examine with mass X-ray apparatus all "males and females between the ages of 15 and 25" no matter where they are—in industry, at school, on the land, or anywhere else, be it in urban or rural communities. Why not use the available man-power and machines to X-ray smaller numbers, but in those groups known to have a higher incidence of disease? The local chest physician is more likely to know these groups and the best method of approach than a highly mobile director of mass radiography.

What is the point of examining with mass radiography such a highly unproductive group as school-leavers without also employing the tuberculin test and B C G vaccine?

A CENTRAL DEFECT

SIR,—Readers of *The Gathering Storm* will remember that one of the first steps taken by Mr Churchill when he took over the Admiralty in 1939 was to form a statistical department, consisting of "half a-dozen statisticians and economists whom we could trust to pay no attention to anything but realities." This gave him, he wrote, "my own sure, steady source of information, every part of which was integrally related to all the rest."[1]

The Ministry of Health, which now has to grapple with a task surely as vast and intricate as that of the Admiralty in 1939, still has no statistical department. Although I shall probably be accused of overestimating the importance of my own profession, I would say that many of the shortcomings of the National Health Service can be traced to this one fact. I suggest, for instance, that the present registrar crisis might not have arisen had the problem been entrusted from the start to statisticians trained to collate and analyse quantitative material in such fields as this.

It is not enough for the Minister to be able to call on the services of such eminent medical statisticians as Dr Percy Stocks and Professor Bradford Hill (great though these services have been). What is needed is a statistical department permanently working on the many problems posed by the N H S, for there can be few problems in a nation-wide health service that have not at least a statistical aspect. It should be the function of the administrative statistician to draw the attention of the policy-maker to trends in, for instance, the probable number of jobless registrars in precisely the same way as the medical statistician draws the attention of the doctors to the increase in, say, the notifications of poliomyelitis, but to perform this function he must be an integral part of the administrative machine, he must be in a position, as was Mr Churchill's statistician, to examine and analyse all the departmental papers with "relentless pertinacity"

---

[1] The Gathering Storm. London 1948, p 368

Is it too much to hope that, in the present crisis of the National Health Service, the Minister of Health will act as decisively as the First Lord of the Admiralty in 1939?

OCCUPATIONAL THERAPY

SIR,—I agree with Dr Herford (Dec 30) that it may be very desirable for the patient to see "the range and number of small crafts to which his hand may be turned for sheer pleasure and joy in creation, perhaps with the added gratification of gifts for friends or furnishing for his home" But is that the sort of therapy which is usually needed, especially by men, who often are anxious to earn a living? Is it not somehow a luxury which we cannot afford at a time when every single hand is needed?

A proper job means much to the man who has been away from his work throughout his illness, with handicrafts many of them feel simply frustrated Return to a "work environment" is what they commonly want

A number of factors have prevented occupational therapy from being converted into industrial therapy (which means being directed more towards the actual future job) the occupational therapist's training would have to be changed, men with practical experience in industrial life, such as the industrial medical officer and the industrial psychologist, would have to be called in, and, of course, positive cooperation from industry itself would have to be the mainspring Here is the crux of the matter The occupational therapy schools have tried to get such help, but on the whole industry has not reacted very favourably To convince industry that industrial rehabilitation—in which the first step is industrial therapy—is really in its own interest will be possible only with the help of the medical profession Vauxhall and Austin in their rehabilitation workshops have given splendid examples of the work which can be done by the creative cooperation of the doctor and the engineer There is no reason why what has been done there should not be done in other industries

"THE LIVER"

SIR,—May we, as the authors, be permitted to comment on your review (Dec 30) of our book?

Because of the novelty of the views expressed we did not expect approbation, but we had hoped for equitable treatment In view of the fact that our bibliography covers over 300 references to published works, and that no fewer than 12 important experimental and original communications by Blond are quoted, it seems at least unfortunate that strictures criticising the lack of *experimental* proof should be directed at this pioneer work

At the same time we should like to direct attention to recent papers and their accompanying pathological findings and photomicrographs dealing with the histology of tissues "in the area of portal hypertension"[1] The salient features of these papers indicate that the ætiology of the two clinical entities of appendicitis and gastric ulcer is unknown, and that none of the current theories explain their causation in a way universally acceptable Study of the photomicrographs accompanying each article makes it clear that the condition is accompanied in its early stages by hyperæmia, and in its more chronic phases by ischæmia It will be agreed by all that the phases of a pathological process accompanied by venous engorgement follow this pattern To this extent we claim that these papers vindicate our hypothesis that the common cause in these two conditions at least is associated with venous engorgement of the veins of these two areas We have, it is felt, demonstrated beyond doubt that the venous drainage of the areas is in fact normally via the portal system It must be conceded that a sudden thrombophlebitis occurring in the venous roots of an organ already the seat of venous engorgement, will lead to a catastrophic state of the organ concerned (in the case of a hollow viscus, to perforation)

Enough has been said here, we feel, to vindicate our theories, and thus allow us to press for careful consideration of the thesis put forward in our work, and to ask that more than "those who enjoy finding the weak spots in a novel argument" should read and carefully appraise our work We are quite confident that those who do so with an unbiased mind will inevitably come to a better understanding of some hitherto unsolved problems in medicine You, Sir, we feel sure, will not lightly allow an original work of challenging unorthodoxy quietly to fail, from lack of publicity We are confident that what our "novel argument" needs more than anything else is intelligent and unbiased criticism—criticism which will look beneath the surface of our hypothesis, and which will not be hidebound by conventions which do not explain but only serve the examinational mind to amass degrees

Even if we cannot persuade reviewers to accept all our views, surely these are not to be condemned *in toto* for that reason

PURIFICATION OF VACCINE LYMPH

SIR,—I read with great interest McClean's[1] article o purification of vaccine lymph and the subsequent correspondence[2] It is evident that all the methods in vogu are essentially in the nature of a compromise, for eithe the potency is affected or the bacterial contaminatio of the lymph is not reduced effectively In this connection I wish to call attention to a new technique, known as the "streptomycin technique," developed by m at the Government Vaccine Institute, Bangalore

This technique is based on the findings of a detaile study made by me on the effects of penicillin and streptomycin on calf lymph[3] These antibiotics were used i a variety of ways both on the vaccinifers and on th prepared lymph at various stages The local application of streptomycin over the vaccinated area of the ca was found to offer an over all advantage The advantage are a high degree of purity, high potency, and reduce cost Further, the method is simple and by far th quickest

Briefly, the method consists in local application of streptomycin solution (10–20 mg per ml in 50% sterile glycer of pH 7 6) over the vaccinated area and its neighbourhoo—in fact over the entire shaved area of the abdomen of th calf—twice a day for five days The first application is mad about 6 hours after infecting the animal with the seed viru and the last about 16–18 hours before scraping When th vesicles are ready for collection they are scraped and triturate with 50% glycerin (1 5) in the usual way The lymp thus prepared is found to have a bacterial count of abou 200 or less per ml —most of them belonging to the *Bacillu subtilis* group of organisms The potency of the lymph *is a* high as 10^{-10} This permits the dilution of vaccine furthe by about 20–25 times

We have been using this technique for the last eigh months with extremely satisfactory results - Moreove his technique, by providing a suitable raw material—namely, vaccine pulp of high purity and potency—should be applicable also to the production of dry vaccine

CELL EMBOLISM AND METASTASIS

SIR,—Your leading article last week refers to Prof J S Young's ingenious experiments demonstrating the mechanical basis which underlies the entry of tumour fragments into blood vessels[1] Professor Young suggests that the extravascular pressure rises above that within the vessels

In examining histological sections of clinically benign vesical papillomata I have been struck by the frequency with which tumour cells can be seen lying inside the vessels They were noted in 7 of the last 19 such specimens in this department, and yet such tumours are seldom disseminated by the blood stream It is possible that the extravascular pressure in these tumours has been raised by the distension of the bladder during cystoscopic fulguration, and this observation might be regarded as confirmatory evidence of Professor Young's thesis

ENDURANCE FEAT BY A YOGI PRIEST

SIR,—There is nothing in the feat described on Dec 23 by Dr Vakil which cannot be very simply explained. It is well known that under hypnosis there is an extraordinarily increased control over the autonomic nervous system, and all the corresponding functions of the body It is easy, for instance, to slow the cardiac and respiratory rate The yogi feat is achieved by self hypnosis

London W 1
S VAN PELT
President of the British Society of Medical Hypnotists

EXTRAPERITONEAL CÆSAREAN SECTION

SIR,—Mr Stansfield and Mr Drabble are to be congratulated on their interesting paper last week, and on their excellent results from extraperitoneal cæsarean section, but someone should sing again the praises of the orthodox transperitoneal approach

During the last twelve years I have dealt by this operation with 54 true emergency cases admitted with obstruction late in labour, in some cases the mother had pyrexia and foul discharge, and the fœtus was dead and stinking I have also dealt with a much larger number—probably twice as many women—in whom trial of labour had failed or who developed obstruction or inertia while under supervision, and who were delivered by orthodox lower uterine segment cæsarean section after labour lasting for forty eight hours or longer I have not yet seen a patient develop peritonitis and none of the women has died

Surely we cannot accept a maternal mortality-rate of 2 5% as a satisfactory standard when the usual transperitoneal operation is used after two days of labour I have indeed tried the extraperitoneal approach on 5 occasions but since in my experience peritonitis is not to be feared after the transperitoneal operation, I have give up any attempt to perfect my extraperitoneal technique Most people would agree that this, by any method, is a more difficult operation, many accidents and dangers have been recorded, and the additional risk involved seems quite pointless The worst complication I have seen after operation upon infected cases has been no more than superficial wound sepsis

Woking
L G HIGGINS

TUBERCULOSIS BEDS IN NORWAY

SIR,—Why not English patients for empty Norwegian sanatorium beds? This question is prompted by the long waiting lists in England and by the elimination in many cases of such lists in Norway, thanks to the sustained efficiency of the campaign against tuberculosis in this country

With a population of only 3 2 million, Norway is now provided with some 5000 beds in sanatoriums, coast hospitals, and "homes" for the tuberculous There are also many beds for the tuberculous in several of the general hospitals staffed by eminent lung surgeons such as Holst, Semb, and Murstad The turnover in sanatoriums has been greatly speeded up by earlier diagnosis and recent advances in treatment, and also by the shuttlecock circulation of patients between sanatoriums and hospitals in which various operations are performed I am informed that at Mesnalien Sanatorium, where I was fortunate enough to undergo artificial pneumothorax treatment as far back as 1908, this shortening and increased efficiency of treatment have set many beds free Other sanatoriums and hospitals staffed by specialists in lung surgery are also ready to receive patients from abroad at charges which are moderate, partly because the Norwegian currency is "soft"

Inquirers interested in the subject should communicate with the Medical Superintendent, Mesnalien Sanatorium, Lillehammer, Norway, or with the Secretary-General of the Norwegian National Association against Tuberculosis, Nasjonalforeningen mot Tuberkulose, Incognitogate 1, Oslo, Norway

Leitet Sunnfjord Norway
CLAUDE LILLINGSTON

EARLY AMBULATION

SIR,—I was most interested in Dr Goodall's article of Jan 6 I should, however, like to join issue with him on the figures he gives for the estimated increased turnover in antenatal and puerperal patients effected by early ambulation

In antenatal wards the majority of patients are suffering from toxæmia The mainstay of the treatment of this condition is still bed rest Ambulation means, as a rule, a return of the hypertension, œdema, and albuminuria Ambulation can be used as a test of progress, and if improvement is maintained it may become possible to discharge the patient, but whether this is early or late does not depend on the wishes or whims of the doctor so much as on the ups and downs of the toxæmic patients under his care

Two other types of patient though not so numerous, probably are responsible for a large number of "blocked beds" in an antenatal ward The first is the cardiac case needing long periods of rest between the 28th week and term and the second is the case of antepartum hæmorrhage—suspected placenta prævia—in which the patient may be admitted for a month or six weeks before the fœtus is large enough to stand a reasonable chance of survival, and therefore before cæsarean section can be performed In the former case obviously any exercise is contra indicated, and in the latter ambulation may easily precipitate a further loss on account of the likely location of the placenta

We would all gladly relieve the pressure on busy antenatal wards, but I am unable to see how Dr Goodall arrives at his figure of a 15% increase in "throughput" In the puerperal wards the increase is estimated at 20% I am afraid that the length of stay in these wards is much more often determined by such problems as slow gain of weight by babies, breast feeding which takes a long time to establish, cracked nipples, and prematurity Ambulation, early or late, does not often play much part in the speed of discharge

---

[1] Young J S Griffith H D *J Path Bact* 1950 62 293

Early ambulation is practised in the obstetric department of this hospital, and we have found the results uniformly satisfactory , but I cannot substantiate the suggestion that this method increases turnover

TH OLBERT

STETHOSCOPES

SIR,—Mr Dickinson's letter of Dec 30 overlooks Glasser's *Medical Physics* (pp 1473–1490) May I add the following considerations to that description and to Mr Dickinson's analysis ?

Sounds depend for quality on the size of the source and its mode of vibration, on the qualities of the ear, and on the characteristics of the intervening space or instrument Further, noises loud enough to drive the ear or other diaphragm into a non linear pressure displacement relationship produce beat-tones not present at the source

The sensitivity of the ear varies with loudness to produce the well known effect of one tone masking the presence of another This effect explains why stethoscopes which do not transmit low notes apparently accentuate high pitched ones

The effect of the wave pattern on the radiating surface upon the quality of the sound is well illustrated in percussion, where, with air laden tissues beneath the chest wall, a comparatively large area depresses as the finger is struck With liquid beneath the surface the tissues at each side of the blow rise up, producing a series of ripples over the chest surface resembling the disturbed surface of a pool into which a stone has fallen The former produces a low frequency note the latter causes cancellation of low notes at the ear For an equal number of vibrations the higher notes die away sooner and sound dull Friction within the tissues also attenuates high frequencies more rapidly The need with loudspeakers for a large baffle if low notes are to be reproduced also illustrates this point

All stethoscopes have diaphragms An artificial diaphragm is useful on an uneven surface, on a flabby surface which would fill a bell, and for quick application to a nervous child Hairy surfaces produce unwanted crepitations with artificial diaphragms A lax diaphragm may be rendered taut by pressure, with resultant modification to the frequency response, for all stethoscopes are—of necessity—acoustic filters transmitting certain tones with greater efficiency than others No frequencies are amplified for the stethoscope is a passive device

Resonance associated with acoustic leaks may provide remarkably good efficiency—i e , impedance matching of a large source to a small ear drum—at a few selected frequencies The common fœtal heart stethoscope and the Laennec stethoscope with their resonant cavities and ill fitting ear pieces are splendid examples of this principle

The efficiency of the Cammann stethoscope in common use depends upon the diameter of the chest piece, upon the volume of dead space which dilutes the vibration pressures, and upon the damping produced by turbid air flow within small bore tubes Few find the instrument insensitive, but those who do may profit from larger bells, from less dead space, and from using only one patent ear tube The tubes should be short and bifurcate near the chin There seems to be an optimum internal diameter around 3 mm

Frequency response depends upon tube length and is alternately maximal and minimal at multiples of a quarter wave length in air There may thus be advantage in using tubes to each ear of different length A leak in the air path in the form of an open side tube, about 10 cm long, reduces the low note response and can be closed by pinching as required A taut diaphragm, or one rendered taut by pressure upon the skin, modifies the frequency characteristic For equal energy transmission the excursion of the diaphragm is inversely proportional to frequency The displacement (x) depends upon the applied force (F) the mass of the diaphragm (M), its stiffness (S), and its effective viscosity or damping (R) according to the general equation, at any instant (t)

$$F = M\frac{d^2x}{dt^2} + R\frac{dx}{dt} + Sx$$

For a sustained note of frequency (f) this becomes

$$\frac{F}{x} = R + j\left(wM - \frac{S}{w}\right) \quad \text{where } w = 2\pi f\text{, and } j = \sqrt{-1}$$

Artificial diaphragms add little mass or damping to the chest wall, but when taut may greatly increase the stiffness which term is seen to diminish in magnitude as the frequency is raised This explains the relatively poor low note response of diaphragm instruments and perhaps too of open bells pressed tightly to the skin

Mr Dickinson's remarks on a rug being gradually compressed may have an explanation in the changed viscosity If he were wishing to compare the transmission properties of a rug with a thick sheet of paper the different ratio of density to Young's modulus and the different order of internal friction damping between strands or molecules would provide an explanation on the above lines This letter, with his, may suggest that there is some value in keeping to one's own stethoscope

NORMAN SMITH

AMIDONE OVERDOSAGE IN A CHILD

SIR,—The possible dangers of amidone ('Physeptone') to children were well illustrated by a case admitted to the children's ward of this hospital on Dec 28

A girl, aged $4^1/_2$ years, had been given 'Linctus Physeptone and Phenobarbitone ,' as symptomatic treatment for suspected whooping-cough, on the afternoon and evening of Dec. [illegible], She took altogether gr 1 of phenobarbitone and 24 mg of physeptone over a period of about 6 hours Next morning her parents found her lying comatose in bed at 8 A M The family doctor brought her up to this hospital, where she was admitted

At that time she was very pale, deeply unconscious, with shallow respiration, narrowly constricted equal pupils, temperature 101°F, pulse rate regular at 172 and respirations 34 per min The fundi showed moderate bilateral papillœdema, without hæmorrhages or exudate No abnormalities were detected in the heart and lungs Both arms and thighs were flaccid, deep reflexes being absent, but there was well marked bilateral ankle clonus and the plantar responses were extensor The urine contained a moderate amount of albumin and a few red cells and granular casts , no sugar Lumbar puncture revealed a clear colourless fluid under pressure, normal in cytology and chemistry The total white cell count was 15,000 (polymorphs 12,600, lymphocytes 2100, monocytes 300) per c mm Her blood urea was 38 mg per 100 ml An X ray film of the chest showed no abnormality A pernasal swab did not grow *H pertussis*

We were fortunate in knowing the exact amounts of the drugs consumed so treatment was begun as follows continuous oxygen , hourly intravenous or intramuscular injections of 2 ml of nikethamide for 6 doses , procaine penicillin intramuscularly to avert lung infection , and an enema of 20% magnesium sulphate solution to reduce intracranial pressure Feeds were given by stomach tube

The child remained unconscious for her first 24 hours in hospital and was drowsy and uncoöperative for a further 48 hours after that A coarse intention tremor became evident as recovery set in, but this lasted only a few days A slight increase in tone was noticed in the left arm but this also passed off The papillœdema had disappeared by the 2nd day The urine was normal by the 4th day The temperature, pulse, and respirations gradually returned to normal by the 6th day At the time of writing, 12 days after her admission, the child is apparently normal in all respects

The average dose of physeptone for an adult is said to be 10 mg three hourly or four hourly, though 30 mg has been given at the same intervals without untoward effect On an age/weight basis, ignoring any possible intolerance during childhood, this child should not have ad more than 2 4 mg four hourly Giving the pheno arbitone at the same time may have enhanced the epressant effects of both drugs

The conclusions to be drawn seem to be (1) that if a D.A. preparation made up in a pleasantly flavoured nctus is prescribed for children, strict precautions gainst overdosage must be taken and (2) that physep one and phenobarbitone may be dangerous in combina ion The case demonstrates once again that giving young hildren cough mixtures containing powerful drugs can e a hazardous step We would be interested to hear f any other cases of coma due to overdosage with hyseptone

We are grateful to Dr C F Harris for encouragement and ermission to report this case

St Bartholomew s Hospital
London, E C 1

R C Roxburgh
D Munro-Faure

*** Messrs Burroughs Wellcome the manufacturers f physeptone linctus, have circulated a letter to all octors suggesting precautions to be taken when pre cribing it for children The properties and dangers of midone are discussed in a leading article on p 156 —Ed L

SMALLPOX AT INFECTIOUS-DISEASES HOSPITALS

Sir,—An account of the outbreak of smallpox at Brighton is given in your issue of Jan 6 Comment is nade upon the poor vaccination state of some members f the staff, and attention is drawn to the memorandum .H.B (50)75, issued in August, 1950

The occurrence of smallpox amongst the nursing staff f the infectious diseases hospital reflects the deplorable tate of the nursing situation in such hospitals at the present time During the past few years infectious-diseases hospitals have been struggling under very grave conditions with the nursing situation in order to admit and care for their patients

As an illustration, figures are given below of the nursing personnel at Lodge Moor Hospital, Sheffield (a similar state of affairs exists, no doubt, all over the country)

Year (December)	*Beds in use*	*Ward sisters*	*Staff nurses*	*Assistant nurses*	*Student nurses*	*Ward orderlies*
1940	378	10	44	11	31	0
1944	460	10	63	2	42	0
1950	360	11	7	9	33	54

7 staff nurses and 54 ward orderlies are performing the nursing functions in 1950 which required 63 staff nurses in 1944 Is this good nursing ? The orderlies are mostly non resident, and are made up of many classes and types of persons, including Germans, Indians, Poles, Austrians, and Italians, supplemented by university students during their vacation Included in the 54 orderlies are 10 males This class of staff is most transitional, the hospital only having their services for short periods—in some instances only for a few weeks—whilst at the same time the hospital is struggling to keep its doors open in order to care for the sick

In order to produce an effective ' iron curtain " around the fever hospital to prevent the spread of smallpox, a more permanent type of staff is required which can be efficiently vaccinated to prevent any spread of the disease should it occur or, unfortunately, be introduced into the hospital

The terms and conditions for nursing staff at fever hospitals are similar to those for staff at general hospitals The latter have the advantages of more attractive work and a more convenient situation , yet no consideration seems to be given to the hardship and risk taken by staff in fever hospitals Surely, there is something radically wrong today in infectious diseases hospitals when we encounter the male adjusting the diapers of the toddler, and when the welfare of our children, stricken with fever, is left to the care of the alien or the ward orderly ?

Lodge Moor Hospital
Sheffield.

Medical Superintendent.

CORTISONE AND INFECTION

Sir,—Recent studies on ' Cortisone ' have dealt with the frequency of spontaneous infections in animals[1] and the possibility of enhancing experimental infections[2]

We have studied the effect of cortisone on experimental granulomatous infection of the rat following the sub cutaneous injection of *Coccidioides immitis* Stiles Post mortem the control rats showed a local tubercle like granuloma without any generalised infection, whereas of 5 cortisone treated animals 3 showed a diffuse infection of the spleen and lungs, the production of connective tissue being greatly inhibited everywhere[3]

INCIDENCE OF SPONTANEOUS INFECTIONS WITH ADMINISTRATION OF CORTISONE

Animal	No of animals	Disorder	Cortisone		No of infected animals
			Daily dosage (mg)	Length of treatment (days)	
Rat	8	Nil	1	70	6
Rat	14	Nil	5	15–20	6
Rat	11	Carbon tetrachloride hepatic cirrhosis	1	20–45	3
Rat	2	Alloxan diabetes	5	15	2
Rat	12	Endocrine kidney	10	10–15	8
Rabbit	4	Nil	10	13	2

In other experiments we have also noted that cortisone determined the appearance of spontaneous infections (see table) necrotic exudative foci were commonly found in lungs, heart and/or liver *Pasteurella muricida* (Meyer and Batchelder) has been obtained from the lesions in the rat

Such pathological findings were never observed either in normal animals or in animals treated with deoxycortone acetate or acetoxypregnenolone under similar experimental and environmental conditions

TREATMENT OF PERFORATED PEPTIC ULCER

Sir,—The late Mr A Hedley Visick, of York, like Mr Hermon Taylor, was stimulated by Bedford-Turner's letter and his own repeated finding of sealed perforations to try out the conservative treatment of acute perforated peptic ulcer His conclusion, based on his own admission on a small number of cases, and published two years before his death (the corrected reference is *Brit med J* 1946, ii, 941), was that if the perforation was small and spillage minimal the cases did well, but that it was in precisely this group of cases that operative mortality was lowest

He too emphasised that the management of these cases was far more exacting without operation, and responsibility for this could not be delegated by the consultant until his staff had had considerable experience of the method It became his practice to operate on all obvious and early cases, and to close the perforation without peritoneal toilet or drainage, reserving watchful conservative treatment for cases where the diagnosis was doubtful, or where the patient was definitely unfit or doubtfully fit for operation With a wise combination of the two methods he hoped to reduce greatly the total mortality There was to be one exception , any case of second perforation was to be treated conservatively and given the benefit of a radical gastrectomy during convalescence, thus obviating an extra operation

[2] Spain D M. Molomut, N *Amer Rev Tuberc.* 1950 62 337
Hart P D A. Rees R J W *Lancet* 1950 ii 301
[3] Redaelli P Cavallero C Borasi M. Sala G Amira A. *Experientia* (in the press)

While the decision as to which is the better treatment for the straightforward case is likely to remain unsettled for many years, two points of practical importance emerge now

1 All cases diagnosed as perforated peptic ulcer should have gastric aspiration carried out in the reception room as soon as they reach hospital If there is delay in admission or a long journey is necessary it should be done by the first doctor to see them after the occurrence

2 Our conception of the prognosis of the patient who is not fit for operation is materially changed

Bristol K D J VOWLES

SIR,—Your issue of Jan 6 contains two more articles supporting, with varying enthusiasm, the adoption of conservative or "aspiration" treatment of perforated peptic ulcer I would support, as I have done before,[1] the cautious attitude expressed in your leading article

Sealing of a perforation of any viscus depends on an interaction of a number of unknown factors Local tissue response to infection, the nature of the infecting organisms, and the individual resistance to these organisms are concerned This plastic fibrinous reaction with or without the local adhesion of omentum is as difficult to forecast in cases of perforated ulcer as in appendiceal inflammation or perforation Mr Stead's case 2 is a perfect example of the failure of this reaction to occur despite the aid of the conservative régime I have seen this failure of local plastic or other sealing action in early or late perforations I am sure it is quite common and it will be recognised much more often (and on the post mortem table) if conservative treatment is widely adopted

Mr Hermon Taylor is I believe, wrong in minimising the risks of incorrect clinical diagnosis The accuracy achieved by his team is above the average In a recent series of 351 consecutive acute abdominal conditions submitted to operation I dealt with 40 perforated ulcers In 4 of these I made the wrong diagnosis pre operatively This compares with DeBakey's figure of 14 5%, representing the diagnostic error in a very large series Acute appendicitis is the commonest mimic of peptic ulcer perforation, and I cannot agree with Mr Stead that a 6 hour delay in operating for this condition is acceptable in any age group

In my 351 cases I further diagnosed perforated peptic ulcer with confidence in 5 cases—at operation quite different conditions were found All required urgent surgery As Mr Hermon Taylor writes, this is a most important problem, but his unusually fortunate experience in this direction minimises its importance

To my mind this high rate of diagnostic error condemns the general adoption of conservative treatment There are many other objections Perhaps it is wise to re state what we hope to achieve by operation Firstly, the diagnosis is confirmed Secondly, by simple suture of the ulcer one arrests a leakage which might otherwise be continuous for many more hours Thirdly, one finds in most cases after operation a patient rapidly and dramatically improved and one who in a very high percentage of cases has a smooth convalescence With all the armamentarium at our disposal I believe the mortality rate should be kept below 5% and the incidence of complications less than that described in the various series treated conservatively

I do not know when dangerous organisms get into the peritoneal cavity Sometimes they may escape in the first gush of gastric or duodenal contents Sometimes they may appear many hours after perforation But I do know that the process is a cumulative one and the sooner it is stopped the better What can aspiration achieve to this end? In gastric perforations I concede that it may on occasion be completely effective In the more frequent duodenal perforations gastric suction may achieve little, and, as Mr Stead rightly points out, it cannot decompress the duodenum, which soon fills with fluid welling up from the inevitable small intestine ileus associated with peritoneal infection Mr Stead recognises this factor but in another paragraph suggests that the "barrier" formed by a "spastic pylorus" is beneficial

Gastric aspiration as an immediate pre operative measure in cases of perforation is of great value Post operative gastric aspiration is an essential adjunct to operative treatment But the conservative régime is quite clearly shown by both Mr Hermon Taylor and Mr Stead to be a ticklish business, and I would deplore its adoption other than in the most exceptional circumstances

Obituary

JAMES SWAIN

C B, C B E, M.D, M S Lond, F.R C S

James Swain was for many years one of the outstanding figures in surgery in Bristol and the west of England Modern surgery in the west may be said to have begun with Greig Smith, who reigned without a rival in hospital and private practice during his too brief career When Greig Smith died at an early age in 1897, James Swain had already been on the staff of the Bristol Royal Infirmary as assistant surgeon for five years, and for a time there was only one other pure consulting surgeon in the town It was the moment when doctors and patients were beginning to realise the great possibilities of surgery in general, and abdominal surgery in particular, and Swain, who was thoroughly competent and had the art of getting on with people without quarrelling, soon found his services in demand over a wide area

[Bright

He came of a Hertfordshire family, and he entered the Westminster Hospital by an entrance scholarship in 1879, qualifying in 1883 Two years later he obtained the London M B with honours, proceeding to the M D in 1887, the F R C S in 1889, and the M S in 1890 After holding resident appointments at the Westminster he became house-surgeon, and then senior resident officer, at the Bristol Royal Infirmary Those were stormy days The students were a particularly turbulent crowd, he was a stranger small of stature, and an inveterate talker, and he had his work cut out to maintain discipline

In 1892 he became assistant surgeon and commenced consulting practice in Clifton After Greig Smith's death it was a nice point who should succeed him as professor of surgery There were two general hospitals in the town bitterly jealous of one another, so it was thought expedient to have a professor from each, and the duties were shared by James Swain and C A Morton They were both good, but not outstandingly good, teachers, and indeed Swain was really too busy to put in a great deal of time with the students In 1909, the University College became the University of Bristol, and he was appointed to the university chair In his earlier years he was a prolific writer, his first paper on perityphlitis appeared in 1885 From 1897 to 1904 he was an associate editor of the *Bristol Medico Chirurgical Journal*, and he also edited the sixth edition of Greig Smith's *Abdominal Surgery*

During the 1914–18 war he became consultant surgeon to the Southern Command, and Bristol saw him but seldom For his services in France as consultant surgeon he was mentioned in despatches and he was appointed C B in 1917 and C B E in 1919 He was one of the British delegates to the inter-Allied congress on the treatment of war wounds which sat in Paris during the later years of the war

He gave up the chair of surgery to Hey Groves in 1920, two years before he reached the age limit, when he retired from practice because of eye trouble He went into the country to live, and became a justice of the peace for Somerset During the past twenty years, he was only occasionally seen at medical functions in Bristol

He married in 1899 Hilda, daughter of Dr A J Harrison, and there is a son and a daughter of the marriage He died on Jan 6, at the age of 88

A R S

GEORGE CLARK CATHCART

M A , M D Edin

Dr George Cathcart, probably the most senior of British otolaryngologists, died at Broadstairs, after a short illness, on Jan 4, at the age of 90 He was born in Edinburgh, the son of James Cathcart, who was the greatest friend of Robert Louis Stevenson's father From Edinburgh Academy and Loretto he went to Edinburgh University, where he graduated M A in 1883 and M B in 1891 After holding a house appointment at Edinburgh Royal Infirmary, he came to London as a resident at the Children s Hospital, Great Ormond Street, later becoming house-surgeon at the old London Throat Hospital In due course he was appointed honorary surgeon to the hospital and after its amalgamation with the Throat Hospital, Golden Square, he was consulting surgeon to that institution He was also appointed consulting laryngologist to the Mount Vernon Hospital, when it was a hospital for pulmonary tuberculosis

Dr Cathcart came of a family of musical enthusiasts He had himself been a pupil at Naples of Scafati last of the teachers of the old Italian *bel canto*, to help to cure a stammer, and his early contributions to medical literature were mainly on problems of voice production He was convinced that the then current English practice of tuning orchestral instruments to the higher concert pitch, instead of French pitch, was one of the chief causes of vocal strain among professional singers, and to prove his point he instituted the famous Promenade concerts at the Queen's Hall, London, with his friend Henry Wood as their conductor He took great pride in the enduring success of the annual series of concerts —though he personally had lost a considerable sum of money in launching them—and of their important influence on musical appreciation in England Particularly while Sir Henry Wood was still alive, he was happy to be an honoured guest at them year after year

In 1926 Dr Cathcart published a revised edition of his friend Hunter Tod's book *Diseases of the Ear* , and as this was then twenty years old, it was largely rewritten It was favourably reviewed, and a year or two later he produced a small book on the *Treatment of Chronic Deafness*, which went into a second edition in 1931 He was convinced of the effectiveness of the electrophonoide method of Zünd-Burguet in the alleviation of deafness In his hands this method undoubtedly achieved good results in many troublesome cases, though treatment had to be repeated once or twice a year He was disappointed that few other otologists persevered with this treatment He was a careful and conscientious surgeon, though his range was not wide, and most of the leading general practitioners in the West End of London reposed their trust in his judgment Freemasonry was almost his religion and he was a past master of the University of Edinburgh lodge and a member of Grand Lodge

" Cathcart was above all a kindly man," writes S H , " and although it is some forty years ago I still remember the warm welcome which he gave me when, knowing little of E N T work, I became an assistant surgeon at the London Throat Hospital He was unquestionably good at his job, but I always looked upon him more as a philosopher than a surgeon He had whimsical inquiring eyes with a sense of humour in them, and a broad outlook with many interests besides his profession Widely read, he was always willing to discuss any new proposals in connection with his work. He was one of the pioneers when otolaryngology was changing from a branch of medicine and taking its rightful place as a surgical specialty "

PHILIP FRANKLIN

F R C S , Hon F A C S

Mr Philip Franklin, the well-known otolaryngologist, died suddenly in London on Jan 7, aged 70 Two days before his death he was lunching at the Royal Society of Medicine, cheerful and volatile as ever, apparently about twenty years younger than his real age, and looking forward to a voyage to South Africa next week

He had had a varied and interesting career Born in San Francisco in 1880, he was educated at Lowell High School there, at Heidelberg, and in London at King's College, King's College Hospital, and Middlesex Hospital In 1907 he took the Conjoint qualification, going on to take the F R C S in 1913

He began his medical career as a research scholar at the cancer laboratories of the Middlesex Hospital, and he went into otolaryngology almost by accident, through meeting a friend in the street who persuaded him to apply for the vacant post of house-surgeon at the old London Throat Hospital, which afterwards amalgamated with the Throat Hospital, Golden Square Franklin later became assistant surgeon at the Metropolitan Ear, Nose, and Throat Hospital and ear, nose and throat surgeon to the Italian Hospital

In 1925 he arranged a successful meeting in London of the Inter State Postgraduate Assembly of North America, and not long afterwards he was proud to have been elected one of the few honorary fellows of the American College of Surgeons Through a friend in Vienna he heard that the famous Onodi collection of anatomical specimens which threw a new light upon the anatomy of the nasal sinuses, was privately in the market, and he acted as secretary and treasurer of a fund which acquired the collection for the museum of the Royal College of Surgeons

Franklin introduced, with considerable success, in the early '30s, the treatment of hay-fever and vasomotor rhinitis by ionisation, but probably his most important work was that connected with the early education of deaf-mutes, on which he published a paper in this journal in 1935 He was then otologist in charge of the research clinic for deaf-mutes at the Infants Hospital, Vincent Square, and he brought new instruments from America, the audio frequency-amplifier and the teletactor, which conveyed vibration stimuli to the ears and finger-tips He considered that these methods should be begun as early as the second year of life and that they hastened the mental development of the deaf-mute infants, encouraged the acquisition of natural voice production, and might even increase residual hearing It was a great disappointment to him that the outbreak of war in 1939 brought this work to an end He himself—at the age of 60—became a major in the R A M C , acting as otologist to military hospitals in the south of England

In 1903 Mr Franklin married Ethel, daughter of the late Mr Lewis White , she died tragically, together with a guest and members of the domestic staff, in a fire at their house in Wimpole Street in 1935 They are survived by a daughter and by two sons—Dr A White Franklin, the pædiatrician, and Dr J L Franklin, the dermatologist

SIR ARTHUR HALL

S R writes " At the first meeting of the Radium Commission, Hall put forward an outstanding conception of its purpose which guided the commissioners for the whole of its life The obligations undertaken by the new body could, he affirmed, only be fulfilled if confidence were established between the commission and the principal radiotherapeutic centres in the country The response to action by the commission on these lines was unanimous and within a year an active impulse ran through the newly established national centres, with inestimable benefit to those suffering from cancer "

Mr Charles West's first wife, who died in 1935, was Miss Esther McCrossan His second wife, whose name we gave incorrectly last week, was formerly Miss Kathleen Thomas

Notes and News

REGISTRARS

In a memorandum on "displaced registrars," the Fellowship for Freedom in Medicine outlines the factors which, in its view, have given rise to the present situation. The memorandum states: "Although the number of hospital beds has not greatly increased since July 1948, the hospital O.P. departments have often been overwhelmed by the patients who previously would have been properly doctored by their G.P.s and would never have sought hospital care. At the same time consultants were no longer encouraged to work the long hours to which they had become accustomed because of the system of payments for a definite number of 3½ hourly sessions a week. Therefore the needs for these trainee consultants was greatly increased." The present situation has been brought about "by the precipitate introduction of the N.H.S., the dislocation of the balance of work between G.P.s and hospitals, and by thoroughly bad planning by the Ministry of Health. The Royal Colleges had been misled into thinking the consultant services were to be expanded to a much greater extent than now seems probable, and they must accept some share of responsibility for the present impasse."

Among the steps recommended by the fellowship are the following: (1) The position of general practice and of the family doctor should be re-established. (2) "It must be possible for some of these 'displaced registrars' to enter general practice and still maintain their interest in hospital work. The present tendency of hospital Regional Boards to abolish G.P. hospitals must cease. The present difficulty would, in considerable measure, be overcome if the buying and selling of the goodwill of general practices were resumed; at the same time private practice should be encouraged, thereby creating a healthy rivalry between the State service and private practice (to the benefit of both)—as has been consistently advocated by the Fellowship." (3) The total number of consultants needed both in the service as a whole and in each specialty should be fixed as soon as possible. "It is absurd to suggest, as the Minister has done, that the number of trainee consultants should be fixed first, and the overall number of consultants laid down at a later date. It is also important to let the profession know which specialties offer the most vacancies in the future, so that a trainee may change from one branch to another in his earliest years." (4) There must be a review of the needs of the service so that the number of registrars needed can be fixed. "Then, over a period of at least two or three years, the present holders of these posts should be encouraged to enter other fields of medicine, if they are not likely to be made consultants in their present field."

The fellowship deprecates the "precipitancy of the Minister's direction that a considerable number of registrars will not have their contracts renewed. It is a waste of valuable experience and of money spent in training, and manifestly unfair to the men concerned. It should be realised that the average age of the senior registrar is 37, and most of them have wives and children." The memorandum concludes that the Minister should withdraw his directive, and consult with all medical interests concerned.

ALL-ROUND HELP

Under the National Health Service responsibility for the care of the patient is shared by different administrative authorities. While he is in hospital he is under the possibly remote wing of a regional hospital board; his new teeth are one of the cares of a local executive council; his home help is, when possible, provided by a local authority. Administratively this division is perhaps inevitable, but the patient does not obligingly respond by dividing his illness into sharply defined stages. The committee set up by the Institute of Almoners, under the chairmanship of Prof. A. L. Banks, F.R.C.P., to consider the patient's care and aftercare wisely point out[1] that the patient still wants the kind of all-round help he used to get in less complicated days from his family doctor. If the health service is to succeed the patient must go on getting this kind of help, and he can only do so if there is effective coöperation between the different parts of the health service. In particular, the almoners consider that the phrase 'care and aftercare' must be widely interpreted for the medical and social needs of the patients are often closely related. The committee recommend that local consultative committees should be set up, composed of doctors, social workers, and local health authority officers, to consider the coördination of medicosocial care of the patient.

---

MEDICAL SERVICES OF THE U.S. ARMED FORCES

The United States department of defence has set up an Armed Forces Medical Policy Council under the chairmanship of Dr. Richard L. Meiling (*New York Times*, Jan. 6). The new council is charged with establishing joint programmes among the three Service medical departments and promoting standardisation of technical activities. Its members include Major General Raymond W. Bliss, Rear Admiral Clifford A. Swanson, and Major General Harry G. Armstrong, surgeon generals of the three Armed Forces. By the medical draft law passed in the last Congress, about 200,000 doctors and dentists under the age of fifty have been arranged in four groups according to their call-up priority. The defence department has now announced that all in priority no. 1 and some in priority no. 2 will be called up by July. The first priority, about 14,000 men, is composed of men who received their education at government expense and who have had little or no active military service. The second priority includes men who received some or all of their education at public expense and who have had comparatively little of active duty.

University of Oxford

On Dec. 16 the following degrees were conferred:

D.M.—J. C. Pease, J. F. Monk.

B.M.—M. J. V. Bull, C. G. Miller, R. M. Morris Owen, W. D. E. Hamilton, J. G. Wallace, J. G. Millar, E. F. H. Murphy, H. E. Milligan, R. G. Mitchell, B. S. Freeman, D. L. Hone, J. K. Pearce, G. M. Scott, J. P. Bingle, J. R. Golding, G. T. Smerdon, G. P. Barn, Constance M. Ridley, Ruth Lister, Jane M. Robinson, Jean McI. Smellie, Diana L. Spencer, Gillian Rowe Dutton, *I. B. Denny, *R. H. Memorial to Mr. Girdlestone

Lord Nuffield has given £10,000 to the Nuffield Orthopædic Centre, Oxford, to found a scholarship in memory of Mr. G. R. Girdlestone, whose obituary we published last week. The scholarship is to enable doctors from overseas to spend some time working at the Wingfield Morris Orthopædic Hospital. Details of the scholarship will be announced later.

Royal College of Surgeons of England

At a meeting of the council on Jan 11, with Sir Cecil Wakeley, the president, in the chair Prof F A R Stammers was admitted to the court of examiners

It was decided to institute a department of pharmacology at an early date

A replica of the master s chair of the Company of Surgeons, which was destroyed by enemy action, was received from Mr V Coppleson and other fellows of the Royal Australasian College of Surgeons

The following diplomas were granted jointly with the Royal College of Physicians

D.A—Frank Alberts B P Armstrong H I O Armstrong Fazlolloh Bakhshayesh Kathleen Blott R C Brown Henry Collier L F G Cruickshank Sylvia Danks Phyllis M de Saram F G Domaingue J R Elliott J R Forsaith Beryl M Goetzee J A Griffiths C C A Jackson P S Jenkin E L Littler P L McGwinn L Y Martin Joan C Mason Gordon Mason Walshaw Rustam Ali Nabi Catherine E D Nash H C Neill D M O Donoghue Maureen O Driscoll J J Polland Marjory A Pollock D R Rigg A R Ryan R C O Saunders E R Sinton Elisabeth B Smith Matthew Spence R J Yale Harinandan Prasad Yarma G J G M Youreh

At the monthly dinner of the college on Jan. 10 brief speeches were made by Sir Godfrey Huggins, F R.C.S (prime minister of Southern Rhodesia), Mr V M Coppleson F.R.C S (Sydney), Prof C A. R Schulenberg F R C S (Pretoria) Dr J L Rowbotham (Boston) and Dr A Bassett (Toronto) An exhibition in the Hunterian Museum had been arranged by Prof Geoffrey Hadfield and the President and Lady Wakeley took a party of guests through the residential college, where some 25 postgraduate students now have temporary homes When the Nuffield College of Surgical Sciences is built on the east side of the college there will be accommodation for 100 postgraduates and visiting surgeons

Society for Cultural Relations with the U S S R

The medical committee of this society is holding a discussion on Monday, Jan 29 at 8 P.M., on Recent Controversies in Soviet Medical Theory based on the work of Pavlov, A. D Speransky, Bykov and O B Lepeshinskaya Dr Leonard Crome is to open the discussion, and Dr J S Horn will also speak. Tickets (1*s* 6*d* members and students 1*s*) may be had from 14, Kensington Square, London W 8

Coördination in the National Health Service

Representatives of local authorities, regional hospital boards, executive councils and the Scottish Health Services Council met in Edinburgh on Jan. 10 for a conference, under the chairmanship of Sir George Henderson, secretary to the Department of Health for Scotland The object was to give those responsible for the day to-day working of the service an opportunity to discuss their experiences and to see whether within the present framework there are any ways in which the local authority services, the general practitioner services and the hospital and specialist service may be better linked. Among the problems discussed were maternity and child welfare the care and treatment of the chronic sick and the tuberculous, the interchange of health records and statistics the reallocation of hospital beds and the relationship of the general practitioner with the hospital specialist It was unanimously agreed that in each area facilities should be provided for convenient and expeditious discussion of all difficulties and problems of coördination at all stages of responsibility for the health service but local initiative should decide how this should best be done—whether by the appointment of special standing committees or otherwise It was also felt to be important that the form of these facilities should be agreed on by the three main partners in the service and that they should be made known to all grades of staff

Superannuation Rights

Medical and dental officers and senior nurses who take a post for not more than three years with the United Nations Organisation or its specialised agencies—such as W.H O or F.A O—or with another intergovernmental organisation may, if they wish retain their superannuation rights under the National Health Service This right will also extend to posts in certain foreign universities and public institutions approved by the Government Further particulars are given in circular R.H B (51)1

Inflation of Practitioners' Lists to be Ended

The Ministry of Health announces that steps are to be taken at once to put on a more accurate basis the records of people on doctors lists National Health Insurance entry cards without National Registration numbers now in the nominal indexes of executive councils are to be matched with the appropriate portion of the local ' live National Registration maintenance registers, and then, by a central clearance operation based on National Registration numbers, duplicate and other redundant entries are to be eliminated Executive councils have been asked to aim at completing this operation by Sept 30 this year While it is being carried out, the Practitioners Fund will be distributed between executive councils according to the number of people on doctors lists at Jan 1 this year

National Dried Milk for Invalids

The Ministry of Food announces that, as supplies of the proprietary brands of infant milk foods are now plentiful, National Dried Milk after Feb 28 will no longer be available to invalids (including patients suffering from steatorrhœa, cœliac disease, and tropical sprue) From that date, national dried milk will normally be reserved for children under 2 years old to whom it is supplied as an alternative to liquid milk at the reduced price of 10½*d* a tin, or free, under the welfare foods service The Ministry will, however, consider granting supplies to children over 2 years of age or to expectant mothers who are normally entitled to liquid milk at 1½*d* a pint or free under the welfare foods service, on presentation of a medical certificate saying that they should have dried milk instead of liquid milk.

Awards for Blood Donors

The Ministry of Health announces that awards are to be made to long service blood donors who have given at least 10 donations of blood since September 1939 Women will receive a brooch and men a lapel badge on which there is a design, which has been approved by the King showing two interlocking hearts surmounted by the crown and resting on a scarlet background There will be three classes of award silver gilt for at least 50 donations, silver for 25 donations, and bronze for 10 donations There are now nearly 400 000 donors in the National Blood Transfusion Service, and it is estimated that about 200 will be entitled to the silver gilt award, 5000 to the silver and 70,000 to the bronze The Princess Royal has consented to present the silver gilt awards on April 3 at the Royal College of Surgeons Forms of application for the award can be obtained from the regional blood-transfusion centre where the donor is enrolled

Community Care Teams

Speaking at the annual meeting of the National Association for Mental Health on Jan. 12 Dr Alfred Torrie the medical director, urged the importance of treating mental illness in homes and factories while still in its early stages This made him regret all the more that since the National Health Service had started the community care teams which the association had previously managed to run in all 12 civil defence regions had been reduced to 2 These teams had put people in touch with social agencies, and by working with the family doctor had often been able to arrange for early help which prevented the development of mental illness They had also halved the relapse rate among people discharged from mental hospitals Field Marshal Lord Montgomery pointed out that morale was a matter of mental health, and that if we had to face grim times the spirit and mind of the nation were weapons which must be kept in good order Sir Otto Niemeyer was able to report that the association had weathered the financial storm which blew up in 1948 when the Ministry of Health s grant of £2000 to local authorities was withdrawn.

International European Society of Hæmatology

A meeting is to be held in Rome in September Further particulars of this society may be had from Dr A Piney, the secretary for Great Britain, 152, Harley Street, London, W 1

Red Cross Unit for Korea

A British Red Cross unit has this month left for Korea, where its tasks will be to alleviate the plight of the homeless by organising the distribution of food and clothing, establishing camps, and planning a medical programme to ensure adequate water and sanitation, to try to prevent disease, and to treat sickness The medical member of the team is Lieut Colonel M C L Smith Similar units are being sent by other national Red Cross societies

French Medical Films

On Tuesday, Jan 30, at 8 15 P M, at the Institut Français du Royaume Uni, 15, Queensberry Place, London, S W 7, the following French films will be shown Patent Ductus Arteriosus (Professor de Vernejoul, Marseilles), Functional Liberation of the Lungs (Dr Warnery and Dr Metras, Sanatorium du Petit-Arbois), Surgical Treatment of Portal Hypertensions (Professor Santy, Lyons), Glosso pharyngo laryngectomy (Professor Portmann, Paris), Psycho surgery—Prefrontal Leucotomy (Professor Wertheimer and Professor Dechaume, Lyons) Cards of admission may be had from the intendant at the institute

---

Dr Chaloem Purananda, secretary of the Thai medical research council and director of the Pasteur Institute at Bangkok, is spending three weeks in this country from Jan 3 to 24, under the auspices of the British Council, visiting medical research institutions and studying recent British developments in electron microscopy

Births, Marriages, and Deaths

BIRTHS

Birt—On Jan 10 in London, the wife of Mr St John Birt F R.C.S—a daughter

JAMES THOMSON
M.B Edin., F.R C.P.E
LECTURER I C DEPARTMENT OF MEDICAL DISEASES OF CHILDREN, UNIVERSITY OF ST ANDREWS, PÆDIATRIC PHYSICIAN, ROYAL INFIRMARY, DUNDEE

FEW reports on non-diphtheritic obstructive laryngo tracheitis and laryngotracheobronchitis have appeared in this country, although during the past thirty years an extensive literature on the subject has grown up in America A recent outbreak in Dundee therefore appears worthy of record.

There is considerable variation in terminology Morgan and Wishart (1947) for instance, use the term acute laryngotracheobronchitis in a wide sense and include within it even cases of spasmodic croup, whereas Kayser (1941), Baum (1945), and others suggest that it should be used only for cases of such severity as to require instrumental relief of respiratory distress The former interpretation seems to be too broad, and the latter too restricted and somewhat unsatisfactory in that such a potentially variable factor as a method of treatment is used in defining it With others acute laryngotracheobronchitis implies the presence of tough viscid secretions throughout the respiratory tract (LeJeune and Bayon 1941) Anatomically we could use three terms obstructive laryngitis, obstructive laryngotracheitis, and obstructive laryngotracheobronchitis From a clinical point of view, however, the difficulty of differentiating in young children between obstructive laryngitis and obstructive laryngotracheitis, without laryngoscopy, leads us to use the one inclusive term, obstructive laryngotracheitis where there is acute laryngeal inflammation associated with signs of persisting respiratory obstruction In obstructive laryngitis, moreover, there is usually some inflammation of the trachea as well (MacCready 1944) We reserve the term obstructive laryngotracheobronchitis for these cases in which, in addition to acute obstructive laryngotracheitis, there is auscultatory or other evidence of bronchitis Further, on the basis of clinical assessment we classify cases as mild, moderate, or severe

THE OUTBREAK

All the cases reported were admitted to the children's wards of the two general hospitals in Dundee, a city of 182,000 inhabitants Although these hospitals serve a regional population of 400,000, no case was admitted from outside the city 22 cases diagnosed as acute obstructive laryngotracheitis or acute obstructive laryngotracheobronchitis occurred within the three months from August to November, 1949 The age incidence was from four months to nine years, and the sex-incidence 68% male and 32% female

Acute laryngeal obstruction was present in all the cases reported but they should be considered against a background of prevalent acute laryngitis and acute laryngotracheitis occurring in the same population at the same time, both in adults and in children, in whom signs of respiratory obstruction were absent or of ins cient severity to warrant admission to hospital quently other members of the family were so affe or had been a few days previously In adults the r complaint was of pharyngeal discomfort, the phar being slightly reddened and appearing granular M cases developed septic tonsillitis about the second or later Although sulphonamide eliminated the se pain was not relieved

The accompanying table sets out the main find and treatment in individual cases In 13 of these a obstructive laryngotracheitis was diagnosed, and acute obstructive laryngotracheobronchitis 9 graded as severe, 7 as moderate, and 6 as mild. condition was not therefore invariably an acute alarming emergency although it was always potent so It will be noted that the grade of severity does necessarily correspond to the amount of respira tract involved

CLINICAL PICTURE

In all cases respiratory distress was of sudden o and in no case had it been present for more than twe four hours before admission One child was brough the casualty department because his mother tho that something had stuck in his throat In some the respiratory distress arose without previous sympt In others there had been a preceding period of a few d and in 2 cases up to two weeks in which coryza a co or some slight hoarseness had been present Sore th and headache were complained of by a few of the children The onset of respiratory distress was gene associated with a croupy cough.

On admission the two outstanding features respiratory distress and prostration The children struggling for breath, stridor, inspiratory and ex tory, was severe, and in many cases there was the lessness, the constant changing of position, and anxious facies associated with anoxia Sleeplessness pronounced Suprasternal recession and indrawin the intercostal spaces and epigastrium were us present Obvious cyanosis was not a feature, but, es ally in the more severe cases there was an ashen pa to which we learned to attach a grave significance, which was not improved by tracheotomy In add to the respiratory distress there was a severe toxa leading to prostration and exhaustion out of propor to the amount of asphyxia present This was particularly in case 20, who died rapidly despite the that a free airway had been established early by trac tomy and was proved at necropsy to have been pres The temperature and respirations varied from 98 4 104 6°F and from 28 per minute to 66 per minute res tively Tachycardia was invariably present Inspec of the throat revealed either no abnormality or mode injection A considerable amount of mucopus occasionally present Where laryngoscopy was perfor it revealed inflammation and œdema of the larynx or without mucopurulent exudate No membrane seen In the first 3 moderate or severe cases this ex nation was made to ensure that no diphtheritic memb was present in the larynx On each occasion respiratory distress and prostration were worse th after, so much so that we became reluctant to use procedure, and it was only used once more (in case during the outbreak It was felt that with the occurr of many similar cases the withholding of laryngosc was justified We do not consider that in sporadic doubtful cases this would be so Examination of chest was often difficult because of the restlessness of patient and the stridor In some cases it revealed no breath sounds, in others diminished air entry, bron vesicular or bronchial breath sounds, rhonchi, or m rales The percussion note was usually resonant Ra graphy showed normal lung fields, bronchitic change, or occasionally terminal bronchopneumonia The white cell count varied from 5000 to 33,000 per c mm , it bore no relationship to the severity or the duration of the illness

Swabs were taken from the pharynx on or shortly after admission and later also from the site of the lesion when feasible They revealed a variety of organisms, none of which seemed to predominate in this outbreak *Corynebacterium diphtheriæ* was isolated from the larynx in case 1 in addition to Friedländer's bacillus, streptococci, and staphylococci, this was proved bacteriologically to be avirulent The child had been previously immunised against diphtheria and had received diphtheria antitoxin without improvement, nor did tracheotomy relieve him There was a profuse mucopurulent exudate in the larynx, trachea, and bronchi We feel justified, in view of these findings and in view of the epidemic occurrence of non diphtheritic respiratory obstruction at this time, in considering that this boy was a diphtheria carrier, and that diphtheria was not responsible for his acute obstructive laryngotracheobronchitis Thomson (1922) has expressed the view that the carrier state may occasionally lead to *C diphtheriæ* being isolated from cases of acute laryngotracheitis of non diphtheritic ætiology Neffson and Wishik (1934) found that in 8% of their cases of non diphtheritic acute laryngotracheobronchitis *C diphtheriæ* was cultured from the laryngeal swab Diphtheria, incidentally, is now rare in this locality

COURSE

The course was short In the 4 patients who died the total duration of illness varied from ten hours to three days, in the patients who recovered, convalescence was established within a week

TREATMENT

Treatment in the main consisted of humidification of the atmosphere and of the administration of oxygen and chemotherapeutic and antibiotic drugs, with attempted instrumental relief of respiratory obstruction in 3 cases The atmosphere in a small side room was humidified with an open steriliser, a relative humidity of 80% being achieved with a room temperature of 75°–80°F Increase in the temperature beyond this level only added to the patient's discomfort Oxygen was supplied through an oxygen tent or on one occasion through a B L B mask The use of these devices had to be limited in certain cases to short periods only, because the patient tended to become very restless and intolerant of them, so much so that in these cases their continued use was likely to add considerably to the exhaustion already present Adequate fluids were given and these were taken well, particularly by the younger children The chemotherapeutic and antibiotic agents used and the dosage given are shown in the table With severe cases later in the epidemic the dosage of penicillin was increased, and in addition 'Aureomycin' was given Cases 12 and 13, both of whom were so severely ill that they did not seem likely to recover, did so on this régime Following the report of Moncrieff and Weller (1949) we had the opportunity to use chloramphenicol in 2 cases, one moderate, the other mild The former patient (case 17) recovered uneventfully, and the latter (case 21), a mongol, died of bronchopneumonia during convalescence from acute laryngotracheitis while still under treatment with chloramphenicol Tracheotomy was done in cases 1 and 20 In case 1 it was done sixty four hours after the onset of symptoms and was followed by intubation through the tracheotomy tube to suck out secretions In case 20 it was done fourteen hours after the respiratory distress first began In case 5 laryngeal intubation with attempted removal of secretions by suction was done seventeen hours after he became acutely ill. These 3 patients died

NECROPSY FINDINGS

Necropsies were done on cases 1, 5, 20, and 21

Macroscopically, inflammation and œdema of the larynx were the outstanding features The inflammation extended to various degrees downwards to the trachea or the bronchi, and upwards into the epiglottis, pharynx, and tonsils The larynx was partly or, in one case, almost completely occluded Mucopurulent exudate was present in various amounts, in the pharynx only, or extending down the respiratory tract even to the bronchioles. In 2 cases areas of purulent necrotic membrane were present in the subglottic region and in the trachea The lungs were involved to a greater or lesser degree, showing either areas of bronchopneumonic consolidation, patchy collapse, and compensatory emphysema, or little change beyond basal congestion Other abnormalities, noted in some cases but not in others, were enlargement of the cervical and tracheobronchial lymph nodes, pallor and flabbiness of the myocardium, and fatty change in the liver

Histologically, there were œdema, hyperæmia, loss of epithelium, and cellular infiltration These changes were maximal in the larynx but occurred also in the trachea, main bronchi, and epiglottis Case 5 had gross necrosis and denudation of the laryngeal mucosa The submucous glands showed catarrhal change only The appearances in the lung indicated aspiration bronchopneumonia, with little interstitial inflammation Where the heart was examined it showed interstitial œdema, without evidence of focal necrosis or of cellular infiltration.

ILLUSTRATIVE CASE RECORDS

Case 3 (moderate) —A boy, aged 22 months On the morning of the day of admission this boy had been noted to be hoarse That evening his breathing had suddenly become laboured and noisy, and stridor had developed He had refused all food He was admitted to hospital four hours later

On admission there was respiratory embarrassment with struggling noisy respiratory efforts and indrawing of the lower part of the chest Stridor was severe, but cyanosis was not present The respirations were 30 per minute The fauces were injected, but no membrane was visible There was uniform expansion of the chest, with a resonant percussion note The breath sounds were diminished and partially obscured by the stridor Radiography showed no abnormality in the lung fields The white cell count was 17,400 per c.mm., the pulse rate 120, and the temperature 99°F

Treatment and Progress —The patient was kept in a steam moistened atmosphere in an oxygen tent and given penicillin and sulphadimidine (see table) After twenty four hours his stridor and respiratory distress were less and his temperature was settling After forty eight hours only hoarseness and occasional cough remained A throat swab showed the presence of hæmolytic streptococci and was negative for *C diphtheriæ* The boy returned home symptom free after nine days in hospital

Case 5 (severe) —A boy, aged 7 years, had first complained of sore throat and malaise twenty four hours before admission He had gone to school the previous day, but that evening had become hoarse and had difficulty in breathing Throughout the night dyspnœa had gradually increased. He had become cyanosed and vomited once or twice

On admission next morning, fifteen hours after the onset of respiratory difficulty, he was extremely pale and appeared toxic His expression was anxious, his intellect clear He was struggling for breath, and although stridor and intercostal indrawing were present they were not extreme His respirations were 45 per minute, temperature 102 4°F, and pulse rate 174. His pharynx was injected and full of mucopurulent secretions.

Treatment and Progress —The patient's colour improved a little after treatment with continuous oxygen through a B.L B mask and with 1 ml of nikethamide intramuscularly Two hours after admission, however, his condition was deteriorating Laryngoscopy showed an inflamed œdematous larynx The vocal cords were seen, and mucopurulent secretion was present Tracheal intubation and aspiration produced no benefit Breathing subsequently became weaker, and the boy became exhausted and apathetic and died six hours after

SUMMARY OF CASES

graphy showed normal lung fields, bronchitic change, or occasionally terminal bronchopneumonia The white cell count varied from 5000 to 33,000 per c mm , it bore no relationship to the severity or the duration of the illness

Swabs were taken from the pharynx on or shortly after admission and later also from the site of the lesion when feasible They revealed a variety of organisms, none of which seemed to predominate in this outbreak *Corynebacterium diphtheriæ* was isolated from the larynx in case 1 in addition to Friedländer's bacillus, streptococci, and staphylococci, this was proved bacteriologically to be avirulent The child had been previously immunised against diphtheria and had received diphtheria antitoxin without improvement, nor did tracheotomy relieve him There was a profuse mucopurulent exudate in the larynx, trachea, and bronchi We feel justified, in view of these findings and in view of the epidemic occurrence of non diphtheritic respiratory obstruction at this time, in considering that this boy was a diphtheria carrier, and that diphtheria was not responsible for his acute obstructive laryngotracheobronchitis Thomson (1922) has expressed the view that the carrier state may occasionally lead to *C diphtheriæ* being isolated from cases of acute laryngotracheitis of non diphtheritic ætiology Neffson and Wishik (1934) found that in 8% of their cases of non diphtheritic acute laryngotracheobronchitis *C diphtheriæ* was cultured from the laryngeal swab Diphtheria, incidentally, is now rare in this locality

COURSE

The course was short In the 4 patients who died the total duration of illness varied from ten hours to three days, in the patients who recovered, convalescence was established within a week

TREATMENT

Treatment in the main consisted of humidification of the atmosphere and of the administration of oxygen and chemotherapeutic and antibiotic drugs, with attempted instrumental relief of respiratory obstruction in 3 cases The atmosphere in a small side room was humidified with an open steriliser, a relative humidity of 80% being achieved with a room temperature of 75°–80°F Increase in the temperature beyond this level only added to the patient's discomfort Oxygen was supplied through an oxygen tent or on one occasion through a B L B mask The use of these devices had to be limited in certain cases to short periods only, because the patient tended to become very restless and intolerant of them, so much so that in these cases their continued use was likely to add considerably to the exhaustion already present Adequate fluids were given and these were taken well, particularly by the younger children The chemotherapeutic and antibiotic agents used and the dosage given are shown in the table With severe cases later in the epidemic the dosage of penicillin was increased, and in addition 'Aureomycin' was given Cases 12 and 13, both of whom were so severely ill that they did not seem likely to recover, did so on this régime Following the report of Moncrieff and Weller (1949) we had the opportunity to use chloramphenicol in 2 cases, one moderate, the other mild The former patient (case 17) recovered uneventfully, and the latter (case 21), a mongol, died of bronchopneumonia during convalescence from acute laryngotracheitis while still under treatment with chloramphenicol Tracheotomy was done in cases 1 and 20 In case 1 it was done sixty four hours after the onset of symptoms and was followed by intubation through the tracheotomy tube to suck out secretions In case 20 it was done fourteen hours after the respiratory distress first began In case 5 laryngeal intubation with attempted removal of secretions by suction was done seventeen hours after he became acutely ill. These 3 patients died

NECROPSY FINDINGS

Necropsies were done on cases 1, 5, 20, and 21

Macroscopically, inflammation and œdema of the larynx were the outstanding features The inflammation extended to various degrees downwards to the trachea or the bronchi, and upwards into the epiglottis, pharynx, and tonsils The larynx was partly or, in one case, almost completely occluded Mucopurulent exudate was present in various amounts, in the pharynx only, or extending down the respiratory tract even to the bronchioles In 2 cases areas of purulent necrotic membrane were present in the subglottic region and in the trachea The lungs were involved to a greater or lesser degree, showing either areas of bronchopneumonic consolidation, patchy collapse, and compensatory emphysema, or little change beyond basal congestion Other abnormalities, noted in some cases but not in others, were enlargement of the cervical and tracheobronchial lymph nodes, pallor and flabbiness of the myocardium, and fatty change in the liver

Histologically, there were œdema, hyperæmia, loss of epithelium, and cellular infiltration These changes were maximal in the larynx but occurred also in the trachea, main bronchi, and epiglottis Case 5 had gross necrosis and denudation of the laryngeal mucosa The submucous glands showed catarrhal change only The appearances in the lung indicated aspiration bronchopneumonia, with little interstitial inflammation Where the heart was examined it showed interstitial œdema, without evidence of focal necrosis or of cellular infiltration

ILLUSTRATIVE CASE RECORDS

Case 3 (moderate) —A boy, aged 22 months On the morning of the day of admission this boy had been noted to be hoarse That evening his breathing had suddenly become laboured and noisy, and stridor had developed He had refused all food He was admitted to hospital four hours later

On admission there was respiratory embarrassment with struggling noisy respiratory efforts and indrawing of the lower part of the chest Stridor was severe, but cyanosis was not present The respirations were 30 per minute The fauces were injected, but no membrane was visible There was uniform expansion of the chest, with a resonant percussion note The breath sounds were diminished and partially obscured by the stridor Radiography showed no abnormality in the lung fields The white-cell count was 17,400 per c.mm, the pulse rate 120, and the temperature 99°F

Treatment and Progress —The patient was kept in a steam moistened atmosphere in an oxygen tent and given penicillin and sulphadimidine (see table) After twenty four hours hi stridor and respiratory distress were less and his temperatur was settling After forty eight hours only hoarseness an occasional cough remained A throat swab showed th presence of hæmolytic streptococci and was negative fo *C diphtheriæ* The boy returned home symptom free afte nine days in hospital

Case 5 (severe) —A boy, aged 7 years, had first complained of sore throat and malaise twenty four hours before admission He had gone to school the previous day, but that evening had become hoarse and had difficulty in breathing Throughout the night dyspnœa had gradually increased He had become cyanosed and vomited once or twice

On admission next morning, fifteen hours after the onse of respiratory difficulty, he was extremely pale and appeare toxic His expression was anxious, his intellect clear He wa struggling for breath, and although stridor and intercosta indrawing were present they were not extreme His respiration were 45 per minute, temperature 102 4°F, and pulse rate 174 His pharynx was injected and full of mucopurulent secretions

Treatment and Progress —The patient's colour improved little after treatment with continuous oxygen through B.L B mask and with 1 ml of nikethamide intramuscularly Two hours after admission, however, his condition wa deteriorating Laryngoscopy showed an inflamed œdematou larynx The vocal cords were seen, and mucopurulent secretio was present Tracheal intubation and aspiration produced n benefit Breathing subsequently became weaker, and the bo became exhausted and apathetic and died six hours afte

All drugs given by mouth unless otherwise indicated.

admission A laryngeal swab yielded a growth of *Staph aureus*, which further investigation showed to be resistant to penicillin and to streptomycin in concentrations attainable therapeutically in the blood and to sulphanilamide, sulphapyridine, sulphadiazine, sulphathiazole, sulphadimidine, and sulphacetamide

Necropsy (Dr H B Goodall) showed an intensely inflamed œdematous larynx partially covered by a cream coloured necrotic membrane The trachea, particularly at the upper end, was involved in a similar inflammation, it contained thick tenacious mucopurulent exudate which extended into the bronchi The larger bronchi were acutely inflamed, and the intermediate ones showed a few areas of catarrh The lungs were the seat of widespread bronchopneumonic change, especially in the posterior parts of the lower lobes Patches of collapse and of compensatory emphysema were a feature The tracheobronchial lymph nodes were enlarged and inflamed The heart showed terminal engorgement of the right chambers *Staph aureus* was also isolated from the heart blood and from the lung in pure culture

Histologically the larynx showed œdema and hyperæmia The mucosa was almost completely necrosed, and there were areas of purulent infiltration into the submucosa, with catarrhal changes in the submucosal glands Even the intrinsic muscles showed dense purulent infiltration The trachea and main bronchi showed changes similar to those seen in the larynx, but less severe Some of the bronchioles were blocked with pus The inflammation in their walls, however, was not sufficiently developed to have caused this degree of purulent exudation, indicating that pus had been aspirated from the upper respiratory tract

Case 12 (severe) —A boy, aged 2 years, had had a slight cough for two days before the sudden onset of severe respiratory distress at 9 P M

On admission two hours later dyspnœa was extreme The respirations were 48 a minute There was obvious indrawing of the suprasternal notch and of the lower anterior half of the chest Breathing was noisy and harsh, with much inspiratory stridor The facies was anxious, and the skin ashen pale The child was restless and, although exhausted, could not sleep His entire energy was concentrated on the effort of respiration, and he seemed oblivious of his surroundings and of those attending him He appeared to be in extremis The fauces were injected, but there was no membrane The expansion of the chest was poor and equal on both sides, with a resonant percussion note and bronchovesicular breath sounds There were scattered coarse crepitations over both lungs Physical examination was otherwise negative The boy s temperature was 100 8°F, pulse rate 150, and white cell count 17,900 per c mm

Treatment and Progress —Continuous oxygen was given in an oxygen tent, and the room atmosphere was moistened with steam Penicillin, sulphadimidine, sulphathiazole, and aureomycin were given as indicated in the table The boy's condition remained unchanged throughout the first twenty four hours During the next twenty four hours some improvement was manifest, although he was still critically ill Thereafter improvement was rapid, with disappearance of all signs of respiratory distress by the fourth day A throat swab taken shortly after admission, but after drug therapy had been started, revealed no bacterial growth Radiography five days after admission showed normal lung fields The patient was discharged home well after seven days in hospital

DISCUSSION

The fact that obstructive laryngotracheitis and laryngotracheobronchitis tend to occur in epidemic form and in association with a high incidence of infection of the upper respiratory tract in the general population has been noted by many workers (Baum 1928, Kayser 1941, Loza 1941, Crooks 1947), and specific epidemics have been described by Smith (1936) and Jeffrey (1945) Gittins (1942), however, states that in twenty two years' experience of acute laryngotracheobronchitis, he has never seen it in epidemic form We have not been able to find any published report of a previous outbreak in Britain

Ætiology

The view has recently gained ground that acute laryngotracheobronchitis is due to a virus, and that secondary invaders follow this (Morgan and Wishart 1947, Neffson 1949) The virus responsible for the acute laryngotracheobronchitis of fowls has been grown when inoculated into the amniotic sac of the chick embryo (Burnet and Foley 1941) When cultured in this manner the virus does not behave in the same way as the influenza virus, which has been suggested as the ætiological agent in human acute laryngotracheobronchitis because of the frequent association of epidemic influenza and this disease Arden and Dulig (1944) suggest that the pathological changes are more in keeping with viral than with bacterial infection Earlier reports favoured particularly the streptococcus as the ætiological agent (Jackson and Jackson 1936), although the disease has been attributed to the staphylococcus (Neffson 1942), *Hæmophilus influenzæ* (Sinclair 1941, De Navasquez 1942, Alexander et al 1942), and other organisms (Neffson 1944) In the 10 cases described by Sinclair (1941), in which *H influenzæ* was isolated from the blood in every instance and from the pharynx in 8 out of the 9 occasions on which a pharyngeal swab was taken, the clinical features and course were very similar to those of this outbreak In our cases the absence of any predominating organism and the short course suggest that a virus was the cause, and the organisms isolated seem likely to have been secondary invaders, which were controlled in most instances by chemotherapy and antibiotic therapy It is noteworthy that in case 5, where *Staph aureus* was cultured from the throat, larynx, pneumonic lung, and blood, this organism was resistant to all the drugs used It will be observed that throat swabs occasionally yielded no growth

Incidence

In this country cases of obstructive laryngitis and laryngotracheobronchitis have been reported by De Navasquez (1942), Thomson (1949), Moncrieff and Weller (1949) and Garson (1950), but they seem to be not so infrequent as the paucity of these reports suggests Age seems to be a predisposing factor to the severer forms, related no doubt to the small size of the infant larynx and to the readily yielding nature of its tissues. The age incidence of the cases reported here follows closely that noted by others (Baum 1928, Smith 1936), as does the sex incidence in its preponderance of males (Bradford and Leahy 1930, Neffson and Wishik 1934, Smith 1936, Bonham Carter 1949)

Clinical Features

The mode of onset and course over the first 24–48 hours were similar to those of many of the American reports A feature of this outbreak, however, was the occurrence in the cases who survived of what almost amounted to a crisis within 24–72 hours, followed by a rapid abatement of symptoms Another feature was the relative absence of complications The combination of these two features made the course of the illness short In many of the reported cases of acute laryngotracheobronchitis, however, the duration of the illness has been measured in weeks Perhaps the specificity of the infecting agent in this outbreak was responsible for the short course, or perhaps chemotherapy modified the primary agent or, as already suggested, controlled secondary invaders The patients who died seemed to do so as much or more from an overwhelming toxæmia as from the asphyxiation associated with respiratory obstruction with its attendant restlessness and exhaustion Saphir (1945) attributes the sudden death in these cases to acute toxic myocarditis and has produced supporting histological evidence

Diagnosis

The sudden onset, the characteristic symptoms, the pyrexia, and the epidemic occurrence made diagnosis of little difficulty in these cases Diphtheria, obstructive laryngitis associated with the exanthemata, laryngitis stridulosa, retropharyngeal abscess, and the possibility of a foreign body in the larynx had to be considered

Jackson and Jackson (1936) state that fulminating acute laryngotracheobronchitis with rapid death may simulate acute bronchopneumonia Neffson (1949) has pointed out that in laryngeal diphtheria the sequence of symptoms tends to be cough, hoarseness, and dyspnœa, whereas in non diphtheritic acute laryngotracheobronchitis it tends to be cough, dyspnœa, and hoarseness The same worker believes that laryngoscopy should be done in every case In 8 of our 22 cases a history of hoarseness preceding or accompanying the onset of respiratory distress was given Like Jackson (1938) we found that a feature of most of our cases was persisting hoarseness after the respiratory distress had gone

Treatment

The development of sudden and severe respiratory distress in a child who has appeared perfectly well a few hours previously presented an urgent and obvious therapeutic problem Owing to the lack of agreement on what constitutes acute obstructive laryngotracheitis and laryngotracheobronchitis, and to the variation of severity in different outbreaks, no close comparison of percentage mortality figures and methods of treatment between one series of cases and another would be valid Different methods of treatment are therefore difficult to compare On certain measures, however, there is general agreement the necessity for a high humidity of the respired air to prevent the secretions from drying and becoming viscid and crusted , the use of oxygen , the giving of adequate fluid , and the contra indication to atropine and to sedatives which are respiratory depressants Regarding humidity Davison (1940) has described the use of a mechanical humidifier rather than the use of steam Brenneman et al (1938) attribute an improvement in their mortality figures after 1935 to the fact that from that date the services of a skilled bronchoscopist were available They advocate tracheotomy in all cases in which it is warranted by the severity of the illness as judged by the general condition of the patient and the findings on laryngoscopy and bronchoscopy Most workers agree that tracheotomy is the most effective method of relieving respiratory distress, either alone or combined with intubation and suction through a tracheotomy tube, or bronchoscopic suction through the tracheotomy wound, to remove tracheal and bronchial secretions Baum (1945) and Neffson (1942), however, favour intubation through the larynx as the method of choice in the first instance, reserving tracheotomy for cases in which this fails Baum (1928) believes that tracheotomy may act adversely by causing drying and viscidity of secretions McEntee (1949), commenting on early tracheotomy, states " Delay will save some tracheotomies and avoid some deaths " We have already referred to the fact that in our cases laryngoscopy, where this was done, was followed by an increase in the respiratory distress, and we have also noted that the two cases where tracheotomy was done and the one case where laryngeal intubation was done were not improved thereby This failure to respond as expected to tracheotomy is in accord with the experience of Sinclair (1941) In most of our cases we relied mainly on the supporting measures already mentioned, combined with chemotherapy and antibiotics This entailed 24–48 hours of anxious conservatism, but we feel that the results justified this course Certainly some of the patients who recovered on conservative treatment appeared to be as severely ill as those who died and on whom instrumental relief of respiratory distress was attempted Rebatta and Martin (1948) state that the introduction of penicillin and sulphonamides has rendered the avoidance of tracheotomy possible in many cases where previously it would have been done Garson (1950) has used streptomycin successfully in one case and aureomycin with similar success in another Of the 5 severe non fatal cases in our series it will be noted that one patient received penicillin plus sulphonamide and the others received those drugs with aureomycin in addition Published reports show considerable divergence of view about the value of sulphonamides and penicillin in this condition The differences in type and in drug sensitivity of the organisms found has to be borne in mind, however Be they primary agents or secondary invaders, they play an important rôle in the disease, and wide variability in the effect of sulphonamides and of penicillin could only be expected The newer antibiotics aureomycin and chloramphenicol with their wide range of activity seem promising weapons requiring further assessment However, in view of our ignorance about the true ætiology of acute laryngotracheobronchitis, and in view of the rapidity with which the condition may prove fatal, a combination of chemotherapeutic and antibiotic drugs seems to offer, for the present at least, a moderately effective if empirical line of treatment

Mortality

The over all mortality in this series was 18%, the mortality among cases classified as severe being 44%

Pathology

The pathological appearances were similar to those usually described in this condition Only 1 of our cases (case 20) was shown at necropsy to have almost complete occlusion of the larynx, and in this case an early tracheotomy had been done In the others there was a reduced laryngeal lumen, which still, however, showed considerable patency There was also evidence of toxic effects on the liver and myocardium These facts seem to emphasise that, although laryngeal obstruction was an important factor, toxic effects were equally so Regarding the nature of the laryngeal obstruction Brenneman et al (1938) and others have laid particular emphasis on the importance of œdema of the loose subglottic tissue Neffson (1949) has drawn a clinical distinction between cases in which this occurs and those, less frequent, in which supraglottic œdema is the main pathological finding The formation throughout the respiratory tract of a membrane consisting of mucopus, desquamated epithelial cells, necrotic mucosa, and later fibrin, is not uncommon (Neffson 1949)

SUMMARY

An outbreak of 22 cases of acute obstructive laryngotracheitis and laryngotracheobronchitis is described

This seems to be the first outbreak of this kind reported in Britain

The epidemiology, ætiology, clinical features, pathology, and treatment are discussed

Chemotherapeutic and antibiotic drugs may, in many cases at least, supplant the surgical measures which have in the past been considered essential in treatment

We wish to thank Prof W J Tulloch and the staff of the department of bacteriology , Prof A C Lendrum, Dr H B Goodall, Dr H G Morgan, and Dr G Nelson of the department of pathology , Mr G I Henderson and Mr J F Mowat of the ear, nose and throat department and Dr W M Jamieson of King s Cross Hospital, Dundee, for their help with investigation and treatment , and Sister Ansell, Sister Crichton, and Sister Wilson for the care and nursing of these patients

ORTHOPÆDIC SIGNS IN THE DIAGNOSIS OF DISC PROTRUSION

WITH SPECIAL REFERENCE TO THE STRAIGHT-LEG-RAISING TEST

JOHN CHARNLEY
B Sc , M B Manc , F R C S
ASSISTANT ORTHOPÆDIC SURGEON, MANCHESTER ROYAL INFIRMARY , LECTURER IN ORTHOPÆDICS, UNIVERSITY OF MANCHESTER

FROM a practical point of view it is possible to distinguish two clinical types of sciatica (1) cases with severe disability, in which the sciatic pain is accompanied by deformity and limited mobility , and (2) cases with only moderate disability, in which mobility is limited only slightly and there is no deformity

In the first type a protruded disc can be diagnosed with certainty by simple clinical tests alone, and the diagnosis can be confirmed by operative findings In the second type a firm diagnosis often cannot be made even with the aid of elaborate radiological techniques, and, even if a protruded disc is found at operation, the result of removal may not show that this was the sole cause of the symptoms

It is an irony of fate that in the first type, where an unequivocal protrusion can almost always be demonstrated, with a nerve root stretched tightly over it, the signs of root pressure are often absent, and even if present are immaterial to the diagnosis , while in the second type, where neurological signs are often the main factor in establishing the diagnosis, surgical exploration of the affected roots often gives disappointing results

The investigation reported here was made to decide to what extent the various signs of deformity and limited mobility might be related to each other

AXIS OF FLEXION AND EXTENSION OF SPINE

Without knowledge of the axis of movement between each pair of vertebral bodies it is impossible to predict the condition of the spinal theca and extradural nerve roots during flexion and extension of the spine When the spine moves from the flexed to the extended position, the space between the vertebral bodies enlarges anteriorly, and that between the spinous processes diminishes posteriorly Though it seems fairly obvious that the axis of movement between each pair of vertebræ must lie near the spinal canal and in the posterior part of the disc, the researches of anatomists have not yet been promulgated in such a way as to convince the practising surgeon that the site of the axis has been conclusively settled , indeed from some reports—e g , Wiles (1935)—it might be concluded that no fixed axis exists, and that the centre of movement changes position in the flexed and extended positions Fick (cited by Steindler 1935), Poirier and Charpy (1926), and Quain (1915) evade direct mention of this point in the course of elaborate descriptions of the mechanics of spinal movement

In investigating the movement of the lumbar spine, with special reference to the movement of the associated dura and extradural roots, the essential feature is not so much the location of an axis of movement *between each pair* of vertebral bodies, if such movement does indeed occur at an axis, but rather the determination of what might be called the " bending axis " for the spine *as a whole* , this is a longitudinal axis which experiences the minimal change in length during transition between the extreme positions of flexion and extension

In the light of this conception of the " bending axis," a new attack was made on the problem by a method which is described here in detail because of its extreme simplicity The procedure is to determine the linear distance between corresponding points on all the vertebræ, measured on X ray films of the spine taken in flexion and in extension Those points situated at a distance from the " bending axis " will either separate from or approximate to each other as the spine moves from flexion to extension, and vice versa , those points which neither separate from nor approximate to each other will therefore lie on the " bending axis " (fig 1)

Method—A fresh lumbar spine was removed from a cadaver, and lateral radiographs were obtained in positions of extreme flexion and extension at a 6 ft tube distance to minimise distortion of measurements To increase the clarity of definition the lumbar spine was bisected in the sagittal plane, only the right or left half being used, with the flat surface laid on the film This bisection did not seem to alter the behaviour of the spine in flexion and extension as compared with the intact specimen The two dry films so obtained, one in flexion and one in extension, were next cut to give curved strips in the following manner to start the first strip, the scissors were carried through corresponding points along the anterior surfaces of the vertebral bodies , the second cut was made by passing through corresponding points in the substance of the vertebral bodies, midway between the front and back surfaces , the third cut passed through corresponding points at the junction of the anterior three quarters with the posterior quarter of the bodies , the fourth cut passed through the posterior surfaces of the vertebral bodies , and the fifth, and last, cut was made through the estimated position of the posterior wall of the spinal canal This produced two series of curved strips of film, one series taken in flexion and the other in extension there being five strips in each series It was now possible to compare, quite accurately, the exact

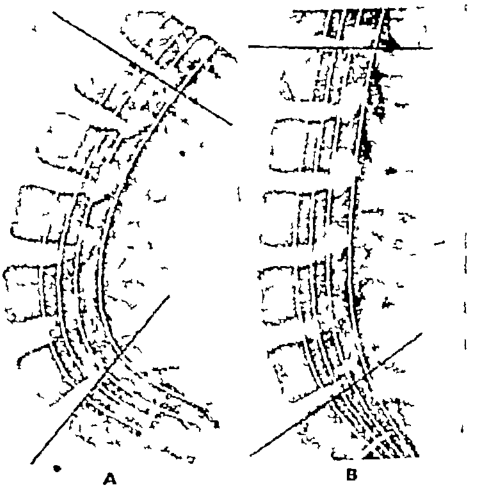

Fig 1—Bending axis of spine A cadaveric spine is radiographed in extension (A) and flexion (B), and lines are drawn through corresponding points in the vertebræ The variation in length of these curved lines can be compared in the extended and the flexed positions Those lines which show the greatest variation in length lie furthest from the bending axis, whereas those which vary least lie nearest to the axis In this specimen the axis of flexion lies about 5 mm anterior to the posterior surfaces of the vertebral bodies

lengths of the convex edges by rolling them against the edge of a ruler, in this way two measurements were obtained for each curve, and the difference in lengths of the same curve in flexion and extension was thereby ascertained The following figures were obtained from a very mobile spine in a person aged 18 and represent maximal figures

Difference in lengths over five lumbar vertebræ of longitudinal parallels passing from flexion to extension

Anterior surfaces of the vertebral bodies increased 12 mm
Mid points of the vertebral bodies increased 3 5 mm
Posterior quarter of the bodies increased 1 mm
Posterior surfaces of the bodies decreased 5 mm
Posterior limit of spinal canal decreased 11 mm

From these figures it is seen that movement was least on a line passing somewhere through the posterior quarter of each intervertebral disc, and therefore this line is to be regarded as the "bending axis" of the spine It will be found from measurements on a vertebra that the bending axis lies about 5 mm anterior to the front surface of the spinal theca

EFFECTS OF FLEXION AND EXTENSION ON SPINAL DURA AND NERVE ROOTS

Attempts to measure relative movement between the dura and spinal canal in the lumbar spine by *direct* observation on the cadaver are unsatisfactory because of the depths of the wound, the difficulty of moving the spine as a result of rigor mortis and body weight, and the small extent of the movements to be expected And, even if these mechanical difficulties could be overcome, such observations would still only concern movement between the dorsal surface of the lumbar theca and the laminæ of the canal The spinal roots emerge from the dura in an anterolateral direction and can be observed only with difficulty in the depths of the canal The plane of the roots lies nearer the posterior surface of the bodies of the vertebræ than the dorsal aspect of the theca, and is thus nearer the bending axis of the spine In the maximal figures obtained in the case described above there was a change in length, between flexion and extension, of 5 mm over the whole length of five lumbar vertebræ measured on the anterior aspect of the theca, whereas corresponding movement measured over the posterior wall of the spinal canal was 11 mm

This difference in mobility of the anterior and posterior surfaces of the lumber theca is reflected in the different anatomical arrangements of these two membranes Being an inelastic membrane, the dorsal dura is lax and relatively redundant, whereas the ventral dura is closely applied to the posterior surfaces of the vertebral bodies without the intervention of any fatty areolar tissue and is rendered immobile by the nerve roots which O'Connell (1943) aptly describes as 'guy ropes which hold the anterior dura against the vertebral bodies"

If the anterior dura is inelastic, as there is every reason to believe, one might wonder how in the lumbar spine it accommodates itself to a change in length of 5 mm between extreme flexion and extension Two possibilities exist either this 5 mm is equally distributed over the whole length of the five lumbar vertebræ, in which case each extradural root has only to accommodate itself to 1 mm of movement in relation to the adjacent bone (in a maximal estimation made on a youthful spine), or, the dura being fixed in the upper reaches of the spine, the range of movement between dura and bony canal becomes cumulatively greater as the distal end of the theca is reached This second possibility is highly unlikely, both on theoretical and anatomical grounds, because this amount of movement would be detectable on gross examination in the cadaver My own observations support the idea that the theca and extradural roots only experience local changes in length corresponding to the adjacent segment of the spinal canal, this behaviour of the theca is therefore quite different from that of the spinal cord and the nerves of the cauda equina, which, as is well known, move a considerable distance in relation to the bony canal during flexion and extension of the spine, and this relative movement becomes cumulatively greater in passing from the foramen magnum to the conus, hence the laxity of the cauda equina

With the theca and nerve roots inelastic, it seems a logical deduction that in the normal spine the total length of dura must equal the length of the anterior surface of the spinal canal when the whole spine is in full flexion, if this is so, all ordinary movements of the spine will take place with a relaxed dura, there is no reason to suppose that the normal dura is ever stretched beyond its maximal length The calculations already mentioned show that the linear changes experienced by the anterior surface of the spinal theca, even for extreme movements, are remarkably small (being near the bending axis) *This therefore explains why a protruded disc can produce more local stretching of the adjacent dura and nerve root than can the local stretch resulting from normal movement between the extreme positions of flexion and extension*

REVERSED LUMBAR LORDOSIS

It is well known that in a severe case of disc protrusion the normal lumbar lordosis is often obliterated, and may even be replaced by a lumbar kyphosis The reasons for this obliteration of the normal hollowing of the lumbar spine offer a most interesting field for speculation

If sciatic pain is caused by *stretching* of the extradural portion of the nerve root (O'Connell 1943) rather than by simple *compression*, a lumbar kyphosis will increase the pain by increasing the tension on the dura One would have expected from the preceding mechanical analysis that the natural protective reaction to stretching of the dura would be to increase the lordosis rather than to abolish it

O'Connell (1943) has attempted to explain reversed lumbar lordosis as a mechanism for relaxing tension in the sciatic nerve and extradural roots in the following words (p 243)

> "If a normal individual is asked to obliterate his normal lumbar lordosis it will be seen that what takes place is a tilting upward of the anterior portion of the bony pelvis with a depression of the sacrum so that the upper portion of the trunk is lowered relatively to the fixed lower limbs Such a movement would have the effect of producing relative relaxation in the roots of the sciatic nerve—the opposite effect to that which follows flexion of the hip or spine"

To the orthopædic surgeon this explanation is untenable In the standing position it is impossible for the normal adult to flatten the lumbar lordosis by backward rotation of the pelvis on the hips, *without at the same*

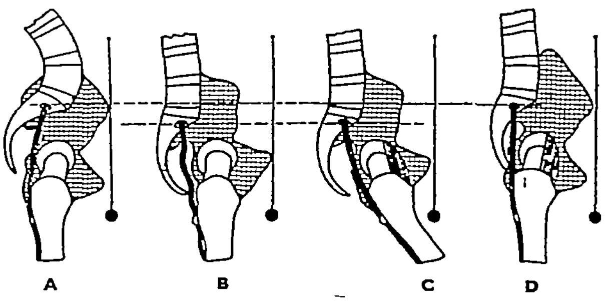

Fig 2—A normal standing position showing pelvis hip-joints, and sciatic nerve in relation to a vertical plumb-line B O Connell s explanation of flattening of the lumbar spine In this theory backward rotation of the pelvis is stated to relax the sciatic nerve C shows the impossibility of the preceding mechanism the pelvis cannot rotate backwards on the hip-joints because of the ligament of Bigelow Flattening of the lumbar spine by backward rotation of the pelvis can only take place if the patient stands with flexed knees. D flattening of the lumbar spine arising locally in the spine as a direct result of altered disc mechanics on this theory flattening of the lumbar spine is not compensatory but tends to stretch the sciatic nerve even further

time flexing the knees, because in the standing position the powerful Y shaped ligaments of Bigelow, which lie in front of the hip joints, are in tension and prevent backward rotation of the pelvis by more than a few degrees (fig 2)

This criticism of reversed lumbar lordosis in disc protrusion as a compensatory mechanism can be further illustrated in a rather different way In a lateral view of the skeleton in the standing position the fifth lumbar vertebra lies almost vertically above the hip joints The sciatic nerve, emerging from the vertebral foramina descends in almost a straight line, through the pelvis posterior to the hip joint If we look on this anatomical arrangement as the face of a clock, with the hip as the centre and the sacrum towards nine o clock, it is apparent that tilting of the pelvis either backwards or forwards on the hip joints so as to move the fifth lumbar vertebra between ten o'clock and two o clock will alter the tension in the sciatic nerve only very slightly (because this region of the clock face, in relation to the direction of the sciatic nerve, corresponds, if one may mix analogies, to a dead centre in the movement of a crank and its connecting rod) If O'Connell s view were correct, it would be necessary for the fifth lumbar vertebra to occupy a position between ten o'clock and eight o'clock if small angles of pelvic tilt were to produce significant changes in the tension of the sciatic nerve It is quite certain that a stance with 10° of hyper extension in the hips, if such a position could be achieved in the adult, would be detectable on clinical inspection

Further evidence that lumbar kyphosis is not a compensatory mechanism to relax the sciatic nerves is suggested by the frequency with which it is associated with pronounced degrees of limitation of straight leg-raising (S.L R) as follows

In 9 cases with *complete reversal* of lumbar lordosis

7 had S L R under 40°
2 had S L R under 60°
0 had S L.R under 80°,
0 had S L R full

In 48 cases with mere *flattening* of the lumbar spine

37 had S L.R under 40
1 had S L R under 60
8 had S L.R under 80°
2 had S L.R full

In 13 cases with normal *hollow* lordosis

5 had S L R under 40
2 had S L.R under 60°,
2 had S L.R under 80 ,
4 had S L.R full

Thus with lumbar kyphosis in all cases the S L R was less than 60° , when the lumbar spine was merely flattened there were nearly four times as many cases with S L.R less than 60° as there were greater than 60° , and with a normal lumbar lordosis the distribution of limited S L R showed no special trend

Another attempt to explain reversed lumbar lordosis as a compensatory mechanism points out that in the flexed position of the spine the intervertebral foramina are increased in size, and therefore any extradural root which is compressed by a protrusion encroaching on the intervertebral foramen would be relieved of pressure by this mechanism This is a tempting speculation, but it has never been convincingly established that compression of a nerve root in the foramen is more than an occasional complication of disc protrusion, and O'Connell's view that tension, rather than compression, is the source of pain is most in keeping with the general clinical picture In compression of the first sacral root by a protrusion from the fifth lumbar disc the first sacral foramen cannot be at fault, because it has no relation to a disc being an intact bony aperture which cannot be encroached on , yet in involvement of the first sacral root there often exists a reversed lumbar lordosis

For these reasons it seems certain that flattening of the lumbar spine in sciatica is not a reflex mechanism evoked to *reduce* tension or pressure in the affected root, and that it is most probably a primary deformity of the lumbar spine resulting directly from altered disc mechanics When the disc protrudes posteriorly, the interval between the posterior margins of the vertebral bodies seems almost to be " jammed open " by the protruded disc, assisted in this by some loss of turgidity of the nucleus pulposus, causing slight collapse anteriorly between the bodies

EFFECT OF FLEXION AND EXTENSION ON DISC PROTRUSION

The effect of flexion or extension on the prominence of a posterior disc protrusion is not generally known In theory the flexed position should increase the protrusion because in this position, anatomists state, the nucleus pulposus moves backwards Begg and Falconer (1949) showed that a protrusion was better revealed by myelography, and therefore was presumably more prominent, when the spine was extended On the other hand, some surgeons operate with the spine in strong flexion (in the knee elbow position) whereas others have the spine almost straight , yet both seem satisfied with their ability to reveal a protrusion It might seem an easy matter to test the effect of flexion and extension at operation, but in practice this observation is very difficult to make unless the movements of flexion and extension can be repeated several times, which is impossible in the operating theatre

It appears, on the whole, that neither flexion nor extension has any great effect on the size of a protrusion, and very few surgeons seem to have observed the so called " concealed disc " of Dandy In all probability, once a disc has been protruded, there is no cavity left for it to retreat into, and the protruded material, being tough and fibrous like boiled lobster and quite unlike the pasty centre of a normal disc, remains stuck in its abnormal position The correct mental picture of a protruded disc is therefore better that of a wedge of solid material driven between the posterior margins of the vertebral bodies rather than that of a fluid hernia which is reducible like a hernial sac in the inguinal canal

Variations, if any, in the size and shape of the protruded disc in flexion and extension, will therefore be direct local effects on the protrusion and not indirect effects communicated to it from the nucleus On extension of the spine the posterior margins of the vertebral bodies will tend to " pinch off " the protrusion, and by relaxation of the overlying annulus fibrosus the protrusion might appear slightly more prominent On flexion of the spine, separation of the vertebral bodies posteriorly might accommodate more protruded material within its own track, and, the overlying annulus fibrosus being rendered tense, might possibly make the prominence seem slightly less obvious Whatever the mechanism, it seems safe to say that moderate variations in the position of the spine make only slight differences to the size of a protrusion and certainly not enough to determine whether a disc will be found at operation or not

STRAIGHT LEG RAISING TEST

Mechanism

Limitation of S L R is well known in sciatica and not uncommonly is recorded in the laconic phrase " Lasègue's sign positive " The tendency to regard this test merely as one of equal significance with four or five other physical signs, from which the final diagnosis is made as an arithmetic sum, is one which needs challenging In its correct perspective the S L R test, when recorded quantitatively in degrees, is of such importance in the diagnosis of disc protrusion—and more particularly in deciding which cases are likely to be benefited by operation—that its value should be regarded as being greater than that of all the other clinical or radiological signs put together To justify this bold statement it is necessary to review our knowledge of the physical basis of the S L.R test

Mechanical Basis of Test

The limitation of S.L.R. can be observed in the cadaver by removing the vertebral bodies from a lumbar spine through the posterior wall of the abdomen until the spinal theca is exposed and the fifth lumbar root is laid bare in its intervertebral foramen. It will then be found that if a straight leg is raised to its full extent (after rigor mortis has been broken down) the nerve root will be seen to move in its foramen as a result of increased tension in the lumbar plexus, and will move by a distance which varies in different cadavers from 0·4 to 0·8 cm. Inman and Saunders (1942) estimated this range at 0·2 to 0·5 cm. and Falconer, McGeorge, and Begg (1948) reported it as 0·2 to 0·6 mm. It will be observed during this experiment that the sciatic nerve behaves as though it were devoid of elasticity, and general experience of the great nerve trunks supports this.

The point I wish to emphasise is not so much that the nerve root moves, or the amount by which it moves, but the *timing* of the movement of the root in relation to the movement of the leg. If movement in the root is closely scrutinised during slow elevation of the extended leg, it will be observed that the root remains quite stationary until the leg has reached an angle of 30° or 40° above the horizontal plane, after which it starts to move quite suddenly and quite briskly and goes on moving with the leg until an elevation of about 70° is reached. Beyond this point further movement of the root is sluggish; and by the time the leg has been raised to 90° the root will have been stationary for some time. This movement of the nerve root in relation to the S.L.R. has been recorded cinematographically by means of a lever recording on a sheet of paper and attached at the other end to the nerve root. The most impressive feature in this direct observation of the movement of the extradural roots in the cadaver, particularly when demonstrated cinematographically, is the suddenness with which the roots start to move.

The sudden start of movement after an initial lag can easily be explained by the taking up of slack in the sciatic nerve during the first arc of S.L.R., but it is not at first clear why the movement, after being brisk during the middle arc, should thereafter tail off again as the leg reaches 90°. The first explanation that comes to mind is that the nerve roots move briskly until the extradural nerve roots become taut, and thereafter no further movement of the root is possible. But this simple explanation is unlikely, because it implies that the nerve-roots in the normal subject are exposed to tension before the completion of S.L.R., and it seems unlikely that normal roots should experience tension except at the most extreme limit of a normal range of movement. The tailing off of movement *without a very pronounced rise of tension* can be explained on the principle of "simple harmonic motion" if the following model is constructed.

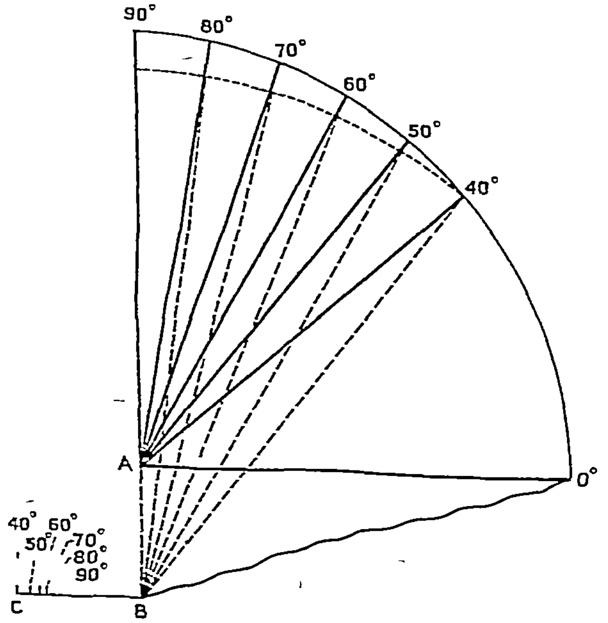

Fig 3—Straight-leg-raising: solid radii from A leg in different posi tions interrupted radii from B sciatic nerve in corresponding positions. When leg is raised to 40° sciatic nerve is taut. Point C, taken in the nerve at the spine, will move towards B as the leg is raised past 40°. Successive positions of C show that movement is fairly rapid from S.L.R. 40° to S.L.R. 60° but slows up for the later positions of the leg.

Experimental Model (fig. 3).—A lath of wood is nailed by one end to a board so that it can pivot on the nail and thereby imitate the pivoting of the straight leg at the hip joint. A second nail is driven into the board near the first nail but separated from it by a distance which represents the separation of the sciatic nerve from the axis of the hip. A piece of string is now tied to the 'foot' end of the wooden lath to represent the nerve and carried behind the second nail to end at a point which represents an intervertebral foramen. It is now necessary to arrange a little slack in the string so that, when the wooden lath is raised to imitate S.L.R., the string becomes tight when the 40° position is attained. The interest now lies in the behaviour of the end of the string representing the nerve root while the wooden lath is raised to 90°. In the working model, as soon as the slack is taken up, the "root" moves rapidly during the middle arc of movement and less briskly when the lath is reaching the end of the S.L.R.

This simple model thus demonstrates that the tailing off of movement in the nerve root is mainly due to the mechanical arrangement of the structures involved in S.L.R. on the principle of simple harmonic motion and that it is unnecessary to suppose that in the normal subject it is caused by a progressive building up of high tension in the root.

Clinical Observations on S.L.R.

It is instructive now to examine the frequency and degree of limitation of S.L.R. in relation to the discovery of a protruded disc at operation.

Of 88 patients operated on the S.L.R. was limited to less than 40° in 63. (The only significance of this preponderance is that it reflects my selection of cases for operation.) Of these 63 patients with such limited S.L.R., 58 (92%) had protruded discs, whereas of the 25 patients with S.L.R. not so limited 16 (64%) had protruded discs. Thus with S.L.R. under 40° exploration proved negative in the proportion of 1 to 11·6 cases, whereas when S.L.R. was over 40° the proportion of explorations proving negative was 1 to 1·8.

Significance of Slight Degrees of Limitations of S.L.R.

The significance of *slight* degrees of limitations of S.L.R. in the diagnosis of disc protrusion needs considerable thought, because it may ultimately prove of the greatest importance in our understanding of sciatic pain.

The observations on the cadaver described above make it difficult to understand the pathological state of the nerve root in a case where S.L.R. attains 90° on the normal side and 80° on the affected side, because in this type of case *the nerve root has already passed its range of greatest excursion without evoking pain or hamstring spasm*. It is conceivable that the involvement of the nerve roots in cases with only slight limitation of S.L.R. might not be of the same direct mechanical origin, caused by a space occupying lesion, as in cases with gross degrees of limitation. It is not impossible that mild degrees of limitation of S.L.R. may be associated with *referred* sciatic pain—i.e., pain which originates in the disc itself even in the absence of a protrusion—and in these cases surgery directed to the removal of pressure *time flexing the knees*, because in the standing position the powerful Y shaped ligaments of Bigelow, which lie in front of the hip joints, are in tension and prevent backward rotation of the pelvis by more than a few degrees (fig 2)

This criticism of reversed lumbar lordosis in disc protrusion as a compensatory mechanism can be further illustrated in a rather different way In a lateral view of the skeleton in the standing position, the fifth lumbar vertebra lies almost vertically above the hip joints The sciatic nerve, emerging from the vertebral foramina, descends in almost a straight line, through the pelvis posterior to the hip joint If we look on this anatomical arrangement as the face of a clock, with the hip as the centre and the sacrum towards nine o clock, it is apparent that tilting of the pelvis either backwards or forwards on the hip joints so as to move the fifth lumbar vertebra between ten o clock and two o'clock will alter the tension in the sciatic nerve only very slightly (because this region of the clock face, in relation to the direction of the sciatic nerve corresponds, if one may mix analogies, to a dead centre in the movement of a crank and its connecting rod) If O Connell s view were correct, it would be necessary for the fifth lumbar vertebra to occupy a position between ten o'clock and eight o'clock if small angles of pelvic tilt were to produce significant changes in the tension of the sciatic nerve It is quite certain that a stance with 10° of hyper extension in the hips, if such a position could be achieved in the adult, would be detectable on clinical inspection

Further evidence that lumbar kyphosis is not a com pensatory mechanism to relax the sciatic nerves is suggested by the frequency with which it is associated with pronounced degrees of limitation of straight leg raising (S L R) as follows

In 9 cases with *complete reversal* of lumbar lordosis

7 had S L R under 40°
2 had S L R under 60
0 had S L.R under 80
0 had S L R full

In 48 cases with mere *flattening* of the lumbar spine

37 had S L.R under 40
1 had S L R under 60
8 had S L R under 80°
2 had S L R full

In 13 cases with normal *hollow* lordosis

5 had S L R under 40
2 had S L.R under 60°
2 had S L.R under 80 ,
4 had S L R full

Thus with lumbar kyphosis in all cases the S L R was less than 60°, when the lumbar spine was merely flattened there were nearly four times as many cases with S L.R less than 60° as there were greater than 60°, and with a normal lumbar lordosis the distribution of limited S L R showed no special trend

Another attempt to explain reversed lumbar lordosis as a compensatory mechanism points out that in the flexed position of the spine the intervertebral foramina are increased in size, and therefore any extradural root which is compressed by a protrusion encroaching on the intervertebral foramen would be relieved of pressure by this mechanism This is a tempting speculation, but it has never been convincingly established that compression of a nerve root in the foramen is more than an occasional complication of disc protrusion, and O'Connell's view that tension, rather than compression, is the source of pain is most in keeping with the general clinical picture In compression of the first sacral root by a protrusion from the fifth lumbar disc the first sacral foramen cannot be at fault, because it has no relation to a disc being an intact bony aperture which cannot be encroached on, yet in involvement of the first sacral root there often exists a reversed lumbar lordosis

For these reasons it seems certain that flattening of the lumbar spine in sciatica is not a reflex mechanism evoked to *reduce* tension or pressure in the affected root, and that it is most probably a primary deformity of the lumbar spine resulting directly from altered disc mechanics When the disc protrudes posteriorly, the interval between the posterior margins of the vertebral bodies seems almost to be "jammed open" by the protruded disc, assisted in this by some loss of turgidity of the nucleus pulposus, causing slight collapse anteriorly between the bodies

EFFECT OF FLEXION AND EXTENSION ON DISC PROTRUSION

The effect of flexion or extension on the prominence of a posterior disc protrusion is not generally known In theory the flexed position should increase the protrusion because in this position, anatomists state, the nucleus pulposus moves backwards Begg and Falconer (1949) showed that a protrusion was better revealed by myelography, and therefore was presumably more prominent, when the spine was extended On the other hand, some surgeons operate with the spine in strong flexion (in the knee elbow position) whereas others have the spine almost straight, yet both seem satisfied with their ability to reveal a protrusion It might seem an easy matter to test the effect of flexion and extension at operation, but in practice this observation is very difficult to make unless the movements of flexion and extension can be repeated several times, which is impossible in the operating theatre

It appears, on the whole, that neither flexion nor extension has any great effect on the size of a protrusion, and very few surgeons seem to have observed the so called "concealed disc" of Dandy In all probability, once a disc has been protruded, there is no cavity left for it to retreat into, and the protruded material, being tough and fibrous like boiled lobster and quite unlike the pasty centre of a normal disc, remains stuck in its abnormal position The correct mental picture of a protruded disc is therefore better that of a wedge of solid material driven between the posterior margins of the vertebral bodies rather than that of a fluid hernia which is reducible like a hernial sac in the inguinal canal

Variations, if any, in the size and shape of the protruded disc in flexion and extension, will therefore be direct local effects on the protrusion and not indirect effects communicated to it from the nucleus On extension of the spine the posterior margins of the vertebral bodies will tend to "pinch off" the protrusion, and by relaxation of the overlying annulus fibrosus the protrusion might appear slightly more prominent On flexion of the spine, separation of the vertebral bodies posteriorly might accommodate more protruded material within its own track, and, the overlying annulus fibrosus being rendered tense, might possibly make the prominence seem slightly less obvious Whatever the mechanism, it seems safe to say that moderate variations in the position of the spine make only slight differences to the size of a protrusion and certainly not enough to determine whether a disc will be found at operation or not

STRAIGHT LEG RAISING TEST

Mechanism

Limitation of S L R is well known in sciatica and not uncommonly is recorded in the laconic phrase "Lasègue's sign positive" The tendency to regard this test merely as one of equal significance with four or five other physical signs, from which the final diagnosis is made as an arithmetic sum, is one which needs challenging In its correct perspective the S L R test, when recorded quantitatively in degrees, is of such importance in the diagnosis of disc protrusion—and more particularly in deciding which cases are likely to be benefited by operation—that its value should be regarded as being greater than that of all the other *clinical or radiological signs* put together To justify this bold statement it is necessary to review our knowledge of the physical basis of the S L R test

Mechanical Basis of Test

The limitation of S.L.R. can be observed in the cadaver by removing the vertebral bodies from a lumbar spine through the posterior wall of the abdomen until the spinal theca is exposed and the fifth lumbar root is laid bare in its intervertebral foramen. It will then be found that if a straight leg is raised to its full extent (after rigor mortis has been broken down) the nerve root will be seen to move in its foramen as a result of increased tension in the lumbar plexus, and will move by a distance which varies in different cadavers from 0·4 to 0·8 cm. Inman and Saunders (1942) estimated this range at 0·2 to 0·5 cm. and Falconer, McGeorge, and Begg (1948) reported it as 0·2 to 0·6 mm. It will be observed during this experiment that the sciatic nerve behaves as though it were devoid of elasticity, and general experience of the great nerve trunks supports this.

The point I wish to emphasise is not so much that the nerve root moves, or the amount by which it moves, but the *timing* of the movement of the root in relation to the movement of the leg. If movement in the root is closely scrutinised during slow elevation of the extended leg, it will be observed that the root remains quite stationary until the leg has reached an angle of 30° or 40° above the horizontal plane, after which it starts to move quite suddenly and quite briskly and goes on moving with the leg until an elevation of about 70° is reached. Beyond this point further movement of the root is sluggish, and by the time the leg has been raised to 90° the root will have been stationary for some time. This movement of the nerve root in relation to the S.L.R. has been recorded cinematographically by means of a lever recording on a sheet of paper and attached at the other end to the nerve root. The most impressive feature in this direct observation of the movement of the extradural roots in the cadaver, particularly when demonstrated cinematographically, is the suddenness with which the roots start to move.

The sudden start of movement after an initial lag can easily be explained by the taking up of slack in the sciatic nerve during the first arc of S.L.R., but it is not at first clear why the movement, after being brisk during the middle arc, should thereafter tail off again as the leg reaches 90°. The first explanation that comes to mind is that the nerve roots move briskly until the extradural nerve roots become taut, and thereafter no further movement of the root is possible. But this simple explanation is unlikely, because it implies that the nerve-roots in the normal subject are exposed to tension before the completion of S.L.R., and it seems unlikely that normal roots should experience tension except at the most extreme limit of a normal range of movement. The tailing off of movement *without a very pronounced rise of tension* can be explained on the principle of "simple harmonic motion" if the following model is constructed.

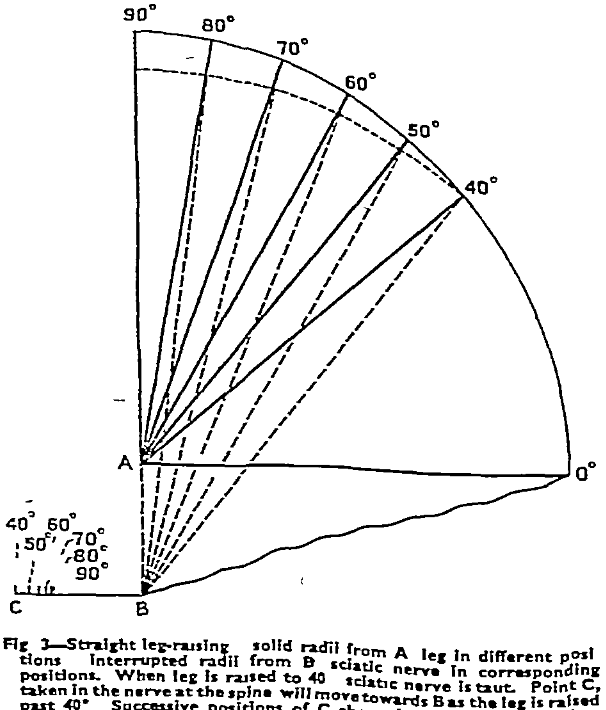

Fig. 3—Straight leg-raising: solid radii from A, leg in different positions; interrupted radii from B, sciatic nerve in corresponding positions. When leg is raised to 40° sciatic nerve is taut. Point C, taken in the nerve at the spine, will move towards B as the leg is raised past 40°. Successive positions of C show that movement is fairly rapid from S.L.R. 40° to S.L.R. 60° but slows up for the later positions of the leg.

Experimental Model (fig. 3).—A lath of wood is nailed by one end to a board so that it can pivot on the nail and thereby imitate the pivoting of the straight leg at the hip joint. A second nail is driven into the board near the first nail but separated from it by a distance which represents the separation of the sciatic nerve from the axis of the hip. A piece of string is now tied to the foot end of the wooden lath to represent the nerve and carried behind the second nail to end at a point which represents an intervertebral foramen. It is now necessary to arrange a little slack in the string so that when the wooden lath is raised to imitate S.L.R., the string becomes tight when the 40° position is attained. The interest now lies in the behaviour of the end of the string representing the nerve root, while the wooden lath is raised to 90°. In the working model as soon as the slack is taken up, the "root" moves rapidly during the middle arc of movement and less briskly when the lath is reaching the end of the S.L.R.

This simple model thus demonstrates that the tailing off of movement in the nerve root is mainly due to the mechanical arrangement of the structures involved in S.L.R. on the principle of simple harmonic motion and that it is unnecessary to suppose that in the normal subject it is caused by a progressive building up of high tension in the root.

Clinical Observations on S.L.R.

It is instructive now to examine the frequency and degree of limitation of S.L.R. in relation to the discovery of a protruded disc at operation.

Of 88 patients operated on the S.L.R. was limited to less than 40° in 63. (The only significance of this preponderance is that it reflects my selection of cases for operation.) Of these 63 patients with such limited S.L.R., 58 (92%) had protruded discs, whereas of the 25 patients with S.L.R. not so limited 16 (64%) had protruded discs. Thus with S.L.R. under 40° exploration proved negative in the proportion of 1 to 11·6 cases, whereas when S.L.R. was over 40° the proportion of explorations proving negative was 1 to 1·8.

Significance of Slight Degrees of Limitations of S.L.R.

The significance of *slight* degrees of limitations of S.L.R. in the diagnosis of disc protrusion needs considerable thought, because it may ultimately prove of the greatest importance in our understanding of sciatic pain.

The observations on the cadaver described above make it difficult to understand the pathological state of the nerve root in a case where S.L.R. attains 90° on the normal side and 80° on the affected side, because in this type of case *the nerve root has already passed its range of greatest excursion without evoking pain or hamstring spasm.* It is conceivable that the involvement of the nerve roots in cases with only slight limitation of S.L.R. might not be of the same direct mechanical origin, caused by a space occupying lesion, as in cases with gross degrees of limitation. It is not impossible that mild degrees of limitation of S.L.R. may be associated with *referred* sciatic pain—i.e., pain which originates in the disc itself even in the absence of a protrusion—and in these cases surgery directed to the removal of pressure from the nerve root is likely to be followed by disappointing results

From our general knowledge of pain arising in deep structures it is not unreasonable to believe that such pain would be evoked on an "all or none principle" and would partake of that quality known in the past as epicritic With pain arising only at 70° or 80° of S L R one can presume that the nerve roots are not already stretched by a protruded disc, the pain is probably evoked in this case by the root being abnormally sensitive to stretching The cause of the increased sensitivity is not necessarily removed by curetting out the adjacent intervertebral disc In other words, I am tempted to suggest that limitation of S L R has two different mechanisms severe limitation to less than 40° implies a mechanical cause extrinsic to the root and evoked by the start of *movement* between the root and the skeletal structures, slight limitation, to not less than 70°, implies a cause of pain intrinsic to the root and evoked by *tension*, because it is not evoked during maximal movement of the root but only when rising tension is to be expected towards the end of S L R

FORWARD FLEXION AND S L R COMBINED

Limitation of forward bending of the spine is a very obvious feature of sciatica To investigate forward bending it is convenient to distinguish five grades of flexion from the erect to the fully flexed position

Grade 1, finger tips reaching 3 in short of the knee caps
Grade 2, finger tips reaching the knee-caps
Grade 3 finger tips reaching 3 in. below the knee-caps
Grade 4, finger tips reaching to mid tibiæ
Grade 5, finger tips reaching to ankles or toes
(Measurements made with knees straight.)

Of the 88 patients operated on, 73 had limitation of forward flexion within the first three grades, of these 73 patients a protruded disc was found in 63 (86%) whereas of the remaining 15 patients with good forward flexion a protruded disc was found in 11 (73%), 4 cases were negative Thus cases with bending limited to the first three grades had a negative exploration in the proportion of 1 to 6 3 cases, whereas cases with bending limited only in the last two grades had a negative exploration in the proportion of 1 case to 2 7 Evidently, therefore, bending alone is not quite so reliable a test for protruded disc as is S L R alone

Further reflection will show that it is impossible to attribute any significance to forward bending without at the same time correlating it with S L R, because forward bending is in fact nothing more than S L R done in the standing position (although certain theoretical differences are superadded by the possibility that the spinal dura is in a different mechanical state, because, when S L R is elicited on a couch, the spine is extended, whereas in forward bending S L R is combined with a flexed spine)

It is perhaps not obvious, unless one has made observations specially with this point in view, how large a part of the movement of forward bending takes place at the hips and how small a part takes place in the spine With a normal person lying supine in the position for the S L.R test the following correlations will be found

20° S L R is roughly equivalent to finger tips reaching 3 in short of knee caps

30° S.L.R. is roughly equivalent to finger tips reaching knee-caps

40° S.L.R. is roughly equivalent to finger tips recahing 3 in below knee-caps

60°–80° S.L.R is roughly equivalent to finger tips reaching mid tibiæ

To touch the ankles or the toes from the supine position is impossible unless the person flexes the neck and raises the shoulders These correlations between S L.R and forward bending are referred to later as being "anatomically consistent"

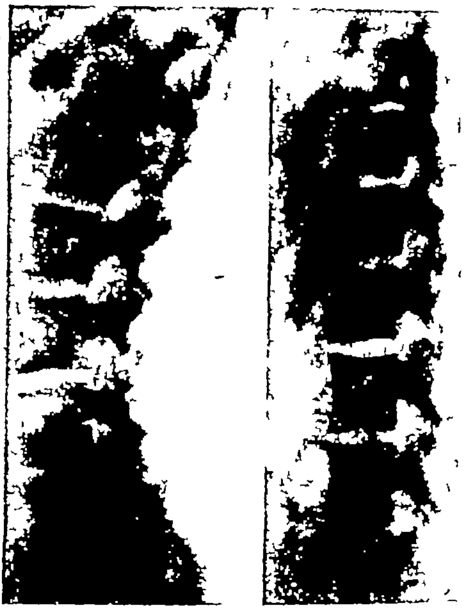

Fig 4—Radiographs showing the relatively small amount of movement which takes place in the lumbar spine between erect stance (A) and full forward bending (B)

Contribution of Spinal Flexion to Total Range of Forward Bending

If a spine is radiographed first in the erect position and next in full forward flexion, a surprisingly small range of movement is shown in the lumbar region In full flexion the lumbar spine never achieves an anterior concavity, at the most the lumbar spine merely becomes straight by the obliteration of the normal lordosis (fig 4) The full range of movement in the lumbar spine probably accounts for only about 20° of forward flexion in an adult without acrobatic powers

This very limited range of movement in the spine is not at first obvious when a patient is seen bending forward to touch his toes, because the strongly flexed position of the head and neck, and the forward drooping of the shoulder blades, reveals the almost fixed curvature of the thoracic spine, which in the erect position is concealed from view It is a common experience to find patients, after fusion of the lumbar spine, whose finger tips reach to the mid tibiæ on forward bending

In the normal person who can easily touch his toes it is not unreasonable to suppose that in this position the sciatic nerves, extradural roots, and spinal dura are at their greatest length and under no abnormal tension

Clinical Observations on Combined S.L.R and Forward Flexion

To decide whether any diagnostic or prognostic significance in sciatica might be extracted from a combined S L.R /flexion relation, it is instructive to construct a chart as in fig 5

In this chart the five grades of forward flexion and the four grades of S.L.R are combined so as to give twenty S.L.R./flexion "boxes", each "box" can be dubbed by the grade of flexion and S.L R it represents in terms such as 90/1, 40/2, &c (meaning 90° S L.R. in a patient with inability to touch his knee caps, 40° S.L.R in a patient able to reach his knee-caps, &c)

By representing each case on the chart as a dot, it is possible to see the distribution of patients in the various "boxes" and by using different symbols to indicate the cases in which a protruded disc was found at operation and those in which it was not, it is possible also to see simultaneously the distri

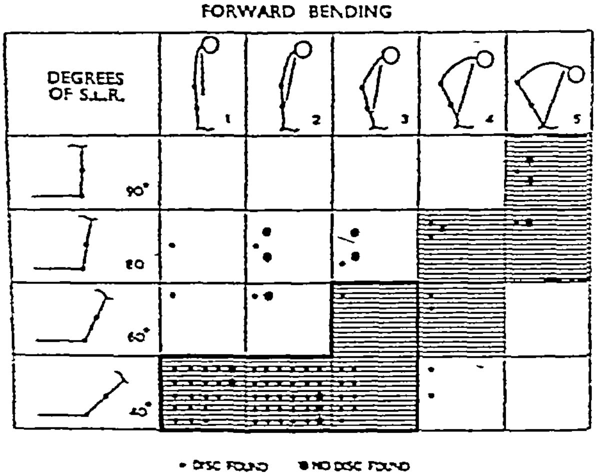

Fig 5—Incidence of protruded discs in relation to S L.R. and forward bending in 68 cases (see text)

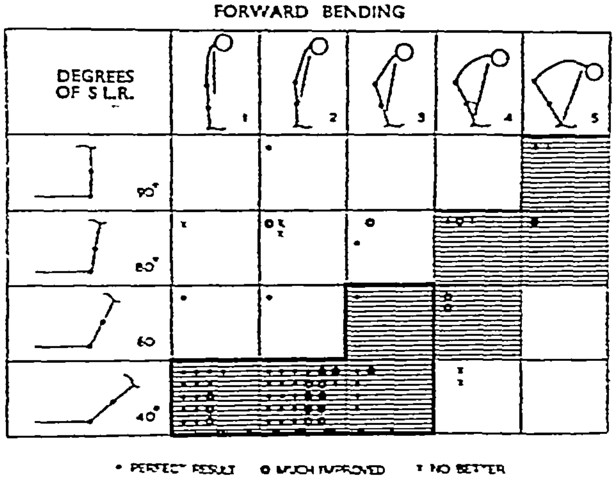

Fig 6—Outcome of surgery in relation to S L.R. and forward bending in 72 cases (see text)

bution of findings at operation in relation to S.L.R and forward flexion.

The shaded boxes represent the combinations of S.L.R. and forward flexion which are anatomically consistent as previously described.

It will also be observed that the first four shaded boxes on the left side of the chart—i.e 40/1, 40/2 40/3, and 60/3—have been further distinguished by being enclosed with a heavy black line These enclosed boxes denote the combinations of S.L.R. and forward flexion which in addition to being anatomically consistent also denote pathological limitation of movement. The remaining boxes which have been shaded but which are not included in the heavy black line denote cases which are anatomically consistent but not necessarily pathological because 90/5 is full flexion in the normal supple young person and 80/4 is normal forward flexion in most middle-aged or stocky patients

After mastering these conventions in the S.L.R /flexion chart it is now possible to review the distribution of cases Disregarding at this moment whether a protruded disc was found at operation or not we can see several broad features

1 On the left side of the chart the physical signs in all the cases were broadly consistent in that there were no cases in which full S.L.R. occurred in combination with very marked limitation of forward flexion—i e , there were no cases in boxes 90/1, 90/2 and 90/3, except for an isolated case in 90/2

2 Similarly, on the right side of the chart the physical signs were broadly consistent in that there were no cases in which full flexion was present in combination with very severe limitation of S.L.R.—i.e , there were no cases in boxes 40/5 and 60/5

3 Most of the cases in the chart fell into the 40° S.L.R group and it is interesting to observe that most of these showed anatomically consistent degrees of S.L.R. and flexion in that they mainly fell into the 40/1 and 40/2 boxes

4. The rest of the cases (except those concentrated in the 40/1, 40/2, and 40/3 boxes) are more or less evenly distributed across the chart without any significant trend though avoiding the boxes denoting extreme inconsistency enumerated in paragraphs 1 and 2

S.L.R /Flexion Relation in Diagnosis

As regards the diagnosis of protruded disc it can be seen that this S.L.R /flexion chart, though raising many interesting features worthy of future study, perhaps does not yield any diagnostic evidence superior to the information gained from the S L.R test alone , it is in relation to negative evidence and the results of operation that the S.L.R./flexion chart is most significant

In the four boxes in the top right hand corner of fig 5—i.e , 90/4, 90 5, 80/4, and 80/5—where minimal limitation of S.L.R. was combined with minimal limitation of forward flexion, no protruded disc was found in 4 cases out of 9

In fig 5 the boxes lying to the left of the " consistent " (shaded) boxes represent those cases in which forward flexion was *less* than might have been expected from the degree of S L.R. discovered in the supine position. Though the figures in the chart are numerically inadequate to prove the point, it seems that when forward flexion is limited more than one would expect from the degree of S.L.R , a protruded disc is unlikely to be found Possibly these patients may be more apprehensive of forward flexion, which they understand, than they are of the S.L.R. test, which they do not understand, and possibly this anomaly implies a psychoneurotic element which disturbs the consistency of the clinical picture

S.L.R /Flexion Relation in Prognosis

It is conceivable that the relation of S.L.R. and flexion to the *results* of operation might reveal the most significant connection , because the results of surgery in the psychoneurotic would probably be poor, whereas on the other hand, " negative " cases, in which a protruded disc was exposed but not recognised, might reveal themselves as good results because the correct mechanical treatment was employed I believe that this is in fact what is found. In S.L.R /flexion chart no 2 (fig 6), it will be seen that out of a total of 49 cases in the " consistent and pathological boxes "—i e , 40/1, 40/2, 40/3, 60/3, and 60 4—only 1 case was ' no better " for the operation. It is significant that after operation this patient revealed herself as a gross hysteric , and, though she was known to be psychoneurotic before the operation, the gravity of her neurosis was not suspected until her behaviour after the operation made it certain.

Out of 14 cases outside the " consistent boxes " plus the 7 cases in the " consistent but not pathological boxes "—i.e., 90/4, 90/5, 80/4, and 80/5—making a total of 21 cases, there were 7 cases no better for the operation Thus the proportion of failures to good results was 1 to 49 in the " consistent and pathological " boxes and 1 to 3 in the " inconsistent " boxes and the " consistent but non-pathological " boxes

Though the numbers in this series are not great their distribution seems significant, and they suggest that the best results of disc surgery are to be obtained when the limitation of forward flexion is anatomically consistent with the amount of S.L.R elicited passively in the supine position.

Possibly inconsistencies in the S.L.R./flexion relation are objective demonstrations of psychoneurosis , but without invoking this too easy explanation it is difficult to explain how a patient should have gross limitation of S L R , less than 40° in the supine position, and still be able to reach to the mid tibia on forward flexion (of the 3 patients in this condition, box 40/4, 2 were no better for the operation) On the other hand, several possible explanations can be offered for the mechanism by which a patient can have S L R on both sides to 80° and yet on forward flexion be only able to reach the knee caps , 4 cases in this category showed three results no better for operation This inconsistency could be explained on psychoneurotic grounds on the theory that the patients' experience in the past has been that forward flexion will cause pain, whereas the S L R test is unknown to them and not associated with apprehension An organic explanation is also possible that in some patients in the standing position the prominence of the protruded disc might be increased by body weight and the root pressure made worse

In the cases which had a consistent S L R /flexion relation, but in which only slight limitation of either was present—i e boxes 90/4, 90/5, 80/4, and 80/5—a high incidence of poor results is perhaps not unexpected, because these boxes contain all the cases within the limits of "normal" physical signs

SCOLIOSIS

Lateral deviation of the spine is a characteristic feature in the clinical examination of many cases of protruded disc, but an analysis of 82 cases, in which scoliosis was found in 39, did not indicate that any particular significance could be attached to scoliosis in rendering certain the subsequent discovery of a protruded disc at operation Of 43 cases without scoliosis, a protruded disc was not found at operation in 9—i e , 1 case in 4 8, or 20%—whereas of the remaining 39 cases with scoliosis a protruded disc was not found at operation in 5—i e , 1 case in 7 8, or 13%

Scoliosis was usually associated with limitation of S L R but it did not yield information as reliable as that obtained from S L R alone, because scoliosis seemed to vary from day to day according to the amount of rest the patient had taken before examination No case of "alternating" scoliosis was encountered in this series, but cases were often seen which had scoliosis one day and none at all the next Scoliosis appeared to subside on rest in bed much more quickly and more completely than limitation of S L R , even though one knew that the protrusion was still present and likely to cause further symptoms if activity was resumed , for this reason, taken by itself, scoliosis is not to be regarded as a reliable sign

SUMMARY

Two clinical types of sciatica are distinguished (1) those with severe limitation of straight leg raising (S L R) which almost always reveal a protruded intervertebral disc and respond well to surgery , and (2) those with slight limitation of S L R which often do not reveal a protruded disc and often show poor results after surgery

The mechanism of S L R test is examined The suggestion is made that where S L R evokes pain under 40° it indicates the *movement* of the root against a protruded disc , and that, when S L R is limited to only 70° or 80° the pain is caused by the start of *tension* on a root which is abnormally sensitive, from causes intrinsic to the root, and not necessarily accompanied by a demonstrable lesion of an intervertebral disc

I am indebted to Sir Harry Platt for reading my manuscript and for enabling me to concentrate on this type of case during the past four years in the orthopædic department of the Manchester Royal Infirmary

ATTEMPTS to relate the incidence of congenital malformations to the season of birth or conception have so far been unconvincing The relevant literature on man scarcely merits detailed comment , it consists of conflicting reports in which numbers are small (Dittrich 1929) or in which insufficient account is taken of seasonal fluctuations in the total numbers of related births (Petersen 1934, Murphy 1936) There have been few observations on experimental animals Landauer (1943) noted seasonal variations in the proportion of malformed chick embryos , and Holt (1948) referred to a similar report by Wright on polydactylism in guineapigs

We have restricted our inquiry to malformations of the central nervous system, which have three advantages for investigations requiring statistical evidence (1) they usually lead to death of the fœtus in utero or shortly after birth and are therefore notified as stillbirths or deaths in the first year of life , (2) they can usually be recognised on external examination, even by persons with no specialised knowledge , and (3) they are common enough to give reasonable numbers—of all malformations notified as stillbirths or first-year deaths about 70% and 40% respectively involve the central nervous system

For investigation of seasonal incidence we have information from two sources (1) the annual reports of the Registrar General for Scotland, which give the causes of stillbirths since 1939 , and (2) observations on 930 consecutive children born in Birmingham in 1940–47 with malformations of the central nervous system

SEASON OF BIRTH

Stillbirths Only

Table I gives for Scotland in 1939–46 the monthly stillbirth rates attributable to fœtal defects The rates for hydrocephalus, spina bifida, and anencephalus are shown separately, and the remaining six subdivisions of fœtal defect included by the Registrar General have been grouped as "other" All but anencephalus show no consistent relationship between incidence and month of birth The group "other" is in any case unsuitable for investigation , and, since many babies with hydrocephalus and spina bifida survive birth, statistics restricted to stillbirths are also unsatisfactory We may therefore turn our attention to anencephalus, which as a cause of stillbirth more nearly satisfies the three criteria of accurate diagnosis, complete returns, and adequate numbers

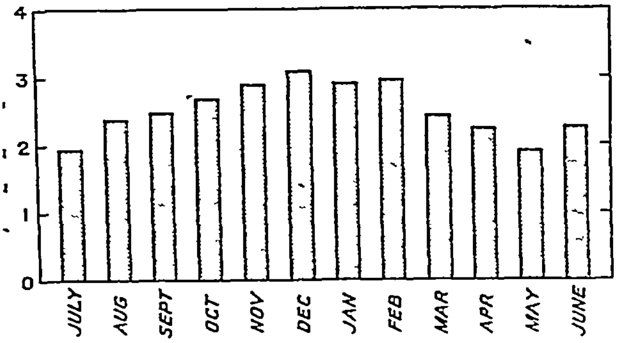

Fig. 1—Monthly stillbirth rates attributed to anencephalus in Scotland in 1939–46

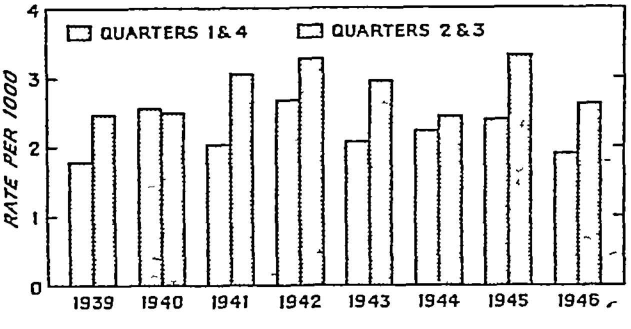

Fig. 2—Half yearly stillbirth-rates attributed to anencephalus in Scotland in 1939–46

The stillbirth rate for anencephalus is lowest in May (1·91) and highest in December (3·09), between these two months the rate increases and decreases fairly regularly (see also fig. 1). Subsequent comparisons are based on quarterly rates, and on half-yearly rates obtained by grouping the second with the third quarter, and the fourth with the first. This choice of groups is arbitrary but was guided by the fact that our data for Birmingham were only available by quarters.†

Table II gives quarterly and half yearly rates for 1939–46 (see also fig. 2). For the whole eight-year period the rates for the half years are 2·20 (second and third quarters) and 2·83 (fourth and first quarters), the difference being 0·63±0·12. With a single exception (1940) each year shows the same result, but because of the smaller numbers the errors of the differences are greater than for the whole period.

Stillbirths and First year Deaths

The Birmingham material has already been fully discussed (Record and McKeown 1949). Briefly, data were recorded for 930 consecutive malformations of the central nervous system certified as the causes of stillbirths or of first-year deaths in the City of Birmingham in 1940–47. Our sources of information were (1) records of the City maternity and child welfare department (available for all 930 malformations), and (2) additional data elicited by field inquiry from 742 mothers who gave birth to 755 children with these malformations. A control group of 876 mothers of children who were not malformed was obtained by selecting every two hundredth name from the registers of live births and stillbirths of the same years and interviews were completed with 742 of these mothers. Table III shows the way in which the 930 malformations have been classified.

Table IV gives for anencephalus, spina bifida, and hydrocephalus quarterly and half-yearly deaths (stillborn and live born) per 1000 births. Since they include first-year deaths, the rates for spina bifida and hydrocephalus may be examined with more confidence than could be justified for the stillbirth rates shown in table I, they show no significant variation. The half yearly rates for anencephalus again show a substantial difference (0·76±0·24), and the examinations which follow of season of conception and of the effect of birth rank are therefore restricted to this malformation. The quarterly rates for Scotland and Birmingham are illustrated in fig. 3.

SEASON OF CONCEPTION

The month of conception is not given for Scottish stillbirths, and, since many of the children with malformations are born before term, it would be wrong to assume that conception took place, on the average, nine months before birth. In the Birmingham inquiry mothers were asked the duration of gestation in months, and the month in which the last menstrual period had occurred was then readily determined from the month of birth. Because the same information was not avail-

TABLE I—MONTHLY STILLBIRTH-RATES (PER 1000 TOTAL BIRTHS) ATTRIBUTED TO FŒTAL DEFECTS (REGISTRAR-GENERAL FOR SCOTLAND 1939–46)

Malformation	Jan.	Feb	Mar	April	May	June	July	Aug	Sept	Oct	Nov	Dec	Total	
													No	Rate

† For 1940–47 Birmingham total births were known by quarters but not by months; hence quarterly but not monthly rates could be calculated.

TABLE III—CLASSIFICATION OF 930 CONSECUTIVE MALFORMATIONS OF THE CENTRAL NERVOUS SYSTEM RESULTING IN STILLBIRTHS OR INFANT DEATHS (BIRMINGHAM 1940–47)

Classified as	Type of malformation	No	
Anencephalus	Anencephalus alone	332	366
	Anencephalus and spina bifida	34	
Spina bifida *	Spina bifida alone	255	389
	Spina bifida and hydrocephalus	129	
	Spina bifida and encephalocele	4	
	Spina bifida, hydrocephalus, and encephalocele	1	
Hydrocephalus	Hydrocephalus alone		150
Other	Encephalocele alone	11	25
	Other central nervous malformations †	14	
Total			930

* Spina bifida includes spinal meningocele, meningomyelocele, and myelocele

† Include microcephaly (8) unspecified congenital cerebral defect (4), and occipital meningocele (2)

able for all related births, seasonal rates cannot be given for conception, and we rely on a comparison of quarterly and half yearly percentage distributions based on the month of the last menstrual periods preceding births of 363 anencephalics and preceding births of 741 controls free from deformities (table v). The proportion of conceptions in the half year from April to September is substantially greater for children with malformations than for controls. Once again it must be emphasised that the choice of quarterly and half yearly figures is arbitrary. For example, the differences revealed in table v would be slightly exaggerated by comparing the half years from March to August and from September to February. We have preferred, however, to preserve the groups used in the earlier tables.

EFFECT OF BIRTH RANK ON SEASONAL INCIDENCE

Before entertaining any alternative explanation for the observed seasonal fluctuation in the incidence of anencephalus, we should consider the effect of birth rank, since we have found that the risk of anencephalus and spina bifida is associated with parity and is highest for first births (Record and McKeown 1949). By expressing the figures in tables I, II, and IV as rates we have taken account of variation in the numbers of total births, we have not allowed for the possibility of seasonal changes in the proportion of births at different parities.

The Scottish data provide no direct evidence on this question. The number of marriages, however, is not constant from month to month, this may influence the relative proportions of first and later births at different seasons. For 1939–46 the number and proportion of marriages in Scotland in each of the four quarters were as follows

First quarter	81,243	(22·26%)
Second quarter	90 406	(24·77%)
Third quarter	102 842	(28·17%)
Fourth quarter	90 554	(24·81%)
Total	365,045	

The mean interval between marriage and first birth is shorter than nine months, and the fact that the percentage of marriages is highest in the third quarter might have some bearing on the high incidence of anencephalus in the winter months.

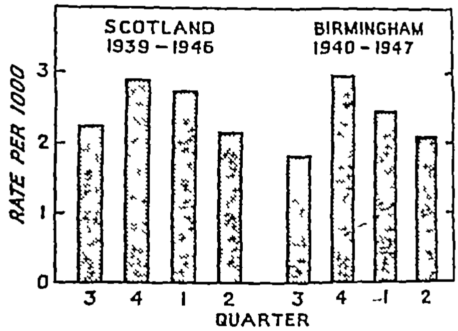

Fig 3—Quarterly stillbirth-rates attributed to anencephalus in Scotland 1939–46 and in Birmingham 1940–47

Birth rank was also unknown for all Birmingham births in 1940–47, but was recorded by field inquiry for 364 anencephalics and 742 controls free from deformities. This information is used in table VI to separate for first and later births the quarterly and half-yearly percentage distributions. For first births the proportion of anencephalics born in the fourth and first quarters was substantially greater than the proportion of controls. The same difference is also exhibited for later births, but is much less striking.

On this evidence it seems unlikely that the seasonal variation in the incidence of anencephalus is explained by changes in the relative proportions of first and of later births. One further point supports this conclusion: the increased risk of malformation associated with first birth was noted for both spina bifida and anencephalus, yet the quarterly and half yearly rates for spina bifida (table IV) show no seasonal differences.

DISCUSSION

There is an interesting difference in seasonal incidence between anencephalus and other malformations of the central nervous system. This may provoke the suggestion that the incidence of anencephalus is related to the seasonal incidence of infectious diseases, but no history

† Abortion rate for mothers of controls = 75 per 1000 known conceptions
‡ Stillbirth rate for mothers of controls = 23 per 1000 births

of a specific fever during pregnancy was elicited from mothers who gave birth to the children with malformations

Data already published (Record and McKeown 1949, 1950a) suggest other biological differences between the three main types of central nervous malformations, and these are summarised in table VII We shall postpone detailed comment until we have presented evidence from a study of 69 pairs of twins exhibiting malformations of the central nervous system (Record and McKeown 1950c) Since attention may be focused on secular trends, we should emphasise that the decline in the annual incidence of anencephalus and spina bifida in Birmingham in 1940–47 may partly be explained by changes in the parity structure of the population of mothers

The evidence obtained in this inquiry suggests that the risk of a later malformation depends to some extent on the type of the first malformation, but numbers do not permit us to speak with confidence on this point, which is therefore omitted from table VII When all malformations of the central nervous system are grouped together, the incidence in later sibs is seen to be about six times greater than the expected rate (table VIII)

TABLE VIII—RISK OF MALFORMATION FOR SIBS BORN SUBSEQUENT TO A CHILD WITH CENTRAL NERVOUS MALFORMATION (BIRMINGHAM 1940–47)

No of sibs	No of malformations		Malformation rate	
	Observed	Expected*	Observed	Expected
470	13	2 12	2 77 ±0 76 %	0 45 %

*For details of the method used to obtain expected numbers of malformations see Record and McKeown (1950b)

SUMMARY

The seasonal incidence of births with malformations of the central nervous system has been examined in material from two sources (1) the annual reports of the Registrar General for Scotland for 1939–46, and (2) records of 930 consecutive malformations of the central nervous system certified as the causes of stillbirths or of first year deaths in Birmingham in 1940–47

The incidence of anencephalus is significantly higher in children born in the half year October–March than in those born in the half year April–September

There is no evidence of seasonal variation in the incidence of spina bifida or of hydrocephalus

It is unlikely that the seasonal variation in the incidence of anencephalus can be explained by changes in the relative proportions of first and of later births This possibility was explored because the risk of anencephalus is higher for first than for later births

The data for anencephalus, spina bifida, and hydrocephalus are tabulated to show the main differences

The incidence of central nervous malformations in sibs born after the birth of a child with such malformation is about six times the expected rate

We are grateful to Miss Catherine Wall and Miss Eileen Gibson for their careful assistance in the preparation of this paper, and to Dr Jean Mackintosh and members of the Birmingham Maternity and Child Welfare Department who made available to us the records of the department

INFECTION OF THE DIGITAL PULP SPACE

T G LOWDEN
B M Oxfd, F R C S
SURGEON, SUNDERLAND ROYAL INFIRMARY

IN the last three years many articles on septic hands have been published Most of them have come from the teaching hospitals, have covered a comparatively short period, have illustrated some special investigation, and have been the personal series of individual surgeons or of a team All have included cases of pulp space infection Some workers (Bolton et al 1947, Webster 1947, Barclay 1949) have classified such cases separately, whereas others (d'Abreu et al 1947) have included them with paronychia Some have illustrated the value of penicillin (Harrison et al 1949), others have shown it to be useless (Webster 1947) All have at least proved that in many centres the septic hand is at last receiving the *attention and skill which its impact on industry demands* The *Lancet* (1947, 1949) and the *British Medical Journal* (1949) have emphasised the value of that attention

But a larger picture should, I believe, be drawn Even with increasing interest and attention, most septic hands *are not treated in teaching centres* by experienced surgeons, with full teaching centre facilities, inpatient accommodation available, and a comparatively leisured operative ritual Nor is it likely, in the immediate future, that they will be I therefore report three years' work in a casualty department where septic hands are treated as an item (albeit an important one) in the daily round, where the majority are operated on by a junior casualty officer (changed at least once in six months), and where the time spent on each case must be kept at a minimum It is not a personal series and it includes all cases with adequate records, whether easily classified or not

With advances in chemotherapy, streptococcal lymphangitis in this clinic has been thrust almost into insignificance A few days' penicillin therapy, sometimes with sulphonamides, has suppressed the "streak" which twenty years ago threatened such serious, sometimes fatal, results The incapacitating lesion which concerns us now is a focal necrosis of fibro fatty tissue, usually due to the staphylococcus Most of even these infections become localised quickly and are relieved by incision, and the patients are fit for work again within a fortnight These infections include the volar compartments (mid and proximal) of the fingers, the "web space" infection, the hair follicle on the dorsum, and most of the subcutaneous infections of the palm and the thenar and hypothenar eminences Penicillin therapy in the early stages may lead to resolution or to limitation of spread, but most patients do not attend early, and late chemotherapy does not then reduce the total period of incapacity

The condition causing the longest incapacity, and often permanent disability, is the pulp space infection With persistence of cavitation the period of incapacity for work averages twenty days, and osteitis of the phalanx, when present, increases the period to fifty one days Of the 438 cases of pulp space infection reviewed in this paper, 72 (16%) developed osteitis (14% in 1947, 22% in 1948, and 12% in 1949) In fact osteitis has been so common and important a mishap that an attempt has been made to consider every possible ætiological factor Here, however, I shall discuss *only those factors* on which, it is hoped, some conclusion can be reached

Kanavel, Iselin, Bunnell, and many others, in standard textbooks, all teach that osteitis is the result of ischæmia of the phalanx caused by the pressure of inflamed tissue on the nutrient vessels passing to the distal two thirds of the bone Bolton et al (1947) and Pilcher et al (1948) question this and regard osteitis as the result of a lymph tic convection, or an infective thrombosis of the vessels standard textbooks also describe a standard incision for ll cases and casualty officers take up their appointment with this incision as their sole weapon against pulp pace infections All authorities agree that infection of bone is established much earlier than X ray evidence ndicates, and it is a short step from there to the comortable assumption that it is established before treatment at the clinic is begun I am not sure that this short step is a safe one

In 1947 and 1948 at this clinic the Kanavel " hockey-stick " incision (single or bilateral) was used in almost all cases There were 6 (barbarous, mutilating, and outspokenly discouraged) " alligators " The pulp space infection was regarded as an emergency, and an early incision was made in 94% of cases 3 cases (6 6%) treated thus within three days of onset developed osteitis Of the late cases 22% developed osteitis Separate analyses for cases treated with and without penicillin showed no significant difference, though penicillin had been given in what is generally regarded as adequate dosage (250,000–300,000 units in oil, b d)

CONSERVATIVE TREATMENT

More recently an attempt has been made to assess the application of the views of Pilcher et al (1948) and of Harrison et al (1949) to a clinic of this type Conservative treatment, as defined by them, consists essentially in complete rest to the whole hand, local applications of dry heat, and penicillin injections It is indicated in cases seen before there is evidence of pus In this clinic the conditions required are obtained in the minority of cases Only 18% of all pulp space infections treated are seen within four days of onset Moreover, the principle of conservative treatment had to be applied cautiously Early disasters almost certainly due to delay in treatment (either outside or inside the clinic) were vivid memories, and an over all reduction of a few days' attendance would be dearly bought if the incidence of osteitis increased even a little I have seen no serious harm done by Kanavel's incision in early cases, though I am prepared to accept that it may be unnecessary I have seen much harm result from delay

TABLE 1—CONSERVATIVE TREATMENT OF CASES SEEN THREE DAYS OR LESS FROM ONSET

—	1948	1949	Duration of symptoms (days)	Days under conservative treatment	Average incapacity (days)	
					1948	1949
Cases ending in resolution	7 (*21%*)	7 (*27%*)	1–3	2–3	6	7
Cases requiring later incision	4 (*18%*)	5 (*20%*)			10	9

Percentages indicate proportion of cases in which conservative treatment was applicable In 1949 8 cases with longer histories were also treated Their results are included in a later table

I have not found that all cases promptly become painless with absolute rest, elevation, splintage and penicillin, and I am reluctant to deny the relief of a well placed incision in cases which do not respond promptly My practice now is to treat early cases (usually three days or less from onset, but mild cases of longer duration) for twenty four hours conservatively and, if they respond, to continue until localisation or resolution takes place. No conservative treatment is continued for longer than twenty four hours if there is not prompt response, nor is it undertaken if it has been strictly but unsuccessfully attempted outside before the case comes to the clinic Harrison et al (1949) found that delay in operating on cases showing significant swelling (they measured the swelling) was unprofitable, and discontinued this part of their investigation I believe that their group showing over 20% swelling corresponds approximately to our clinical group of those who do not respond to twenty four hours' conservative treatment, and I am therefore in agreement with them If incision is necessary in successful conservative cases, a local incision is made, only the abscess cavity is decompressed, and healing is rapid Incision in those not responding within twenty-four hours is usually a single hockey stick incision, almost but not quite " through and through "

The results of this approach to early cases are set out in table I The percentages indicate the proportion of early cases in which conservative treatment was applicable The majority required immediate incision

OSTEITIS

Osteitis of the distal phalanx resulting from pulp space infection may be divided into three fairly well differentiated types

Type I —Not infrequently a terminal subonychia is associated with necrosis of the adjacent part of the nail bed and pulp This may lead to osteitis of the tip of the phalanx Unroofing the area (the roof includes some nail as well as cuticle) is followed by rapid resolution, and there is no tendency to spread It causes no permanent disability and does not greatly prolong incapacity It accounted for 30 % of osteitis cases in the whole period To include these cases in a general analysis of osteitis gives optimistic figures

Type II —Pulp-space infection which does not localise promptly may lead to a superficial osteitis—not merely a periostitis, as often described—in the volar surface of the phalanx Judging by its radiological appearances, this may well be brought about by convection of infection from the pulp space by lymphatics The bone seldom if ever sequestrates, but the osteitis prolongs the incapacity period 21 % occurred in the series

Type III —Massive necrosis with the formation of a sequestrum occurs in our series too frequently (45 %) Not only does it take the longest time to heal but also it is the only type leaving a permanent bony deformity In some the mechanism is clear The patients come to their first attendance with a bag of pus ' Exploration reveals a thin crust of true skin and nail bed with the phalanx holding up the middle like a tent-pole Vessels are destroyed on all sides, and loss of most of the phalanx is almost inevitable

I further divide all cases of osteitis into those established when first seen at the clinic, and those developing during treatment My criteria for the former are (1) observation, at operation, of destruction (not merely exposure) of bone, (2) X ray evidence, or (3) spontaneous sequestration within the first ten days' treatment I regard all the rest as late cases, for them I blame myself, and in treating them I hope to improve In 1947 we had 4 cases sequestrating late in the course, in 1948 we had 9, and in 1949 we had none Types I and II of osteitis occurring late have shown no sign of improvement yet

CENTRAL SINUS

Iselin (quoting Klapp) states that a central sinus indicates osteitis of the phalanx I have not found this so Only 19 of 59 cases presenting with, or developing, a central sinus had osteitis, 6 had massive necrosis (type III)

I suspect that many cases presenting with a central sinus, developing one under conservative treatment, or having extensive destruction of soft tissues anywhere in the pulp, *develop* osteitis when hockey stick incisions are added to the existing destruction Hockey stick incisions are bound to cut across what few vessels remain between healthy tissue and the volar surface of the phalanx, and I now regard the appearance of superficial pus near the midline as an absolute contra indication to classical drainage In these cases the volar scar is inevitable and, as other workers have already said, the volar drainage is usually adequate Nearly all late cases are now treated by removal of cuticle, evacuation of pus and loose slough, and drainage of all infected spaces through the hiatus I do not excise adherent slough

I suspect, in fact, that any *unnecessary* incision increases the jeopardy in which the phalanx lies—e g , the removal of nail because of redness and swelling of the nail fold—but I have insufficient cases (fortunately) to support me

In this late type of case, which is so common a problem in our department, we consider the Kanavel incision definitely harmful Previous writers have, I think, failed to emphasise this Their condemnation applies to early cases, in which I think it may still have a place My figures were as follows

Condition and treatment	*No of cases*	*Late osteitis*
Central sinus and hockey stick or other incision	47	11 (23%)
Central sinus and local drainage	12	1 (9%)

CAVITATION

The discharge or release of pus, and the separation of slough, leave a cavity in the pulp space which fills with granulations and heals We always have one or two patients attending with infection apparently overcome, and a clean cavity *lined* by granulations but reluctant to fill with them, having overhanging walls and often an area of viable bone also covered with granulations in its base These cavities may persist for two or three weeks

Gibbs (1948) states that delay in the collapse of cavity walls is due to penicillin therapy, which sterilises but does not dispose of the abscess and encourages delay in surgical drainage In the present series by no means all the cases showing this delay had had penicillin The problem is usually mechanical The cavity is often held open by the healthy bone, rather than prevented from healing, as many suppose, by unhealthy bone in its base It is sometimes held open by the nail, and cutting the nail as far back as possible helps in these cases In most there is no answer, short of deliberately undertaking a plastic operation (a miniature " thoracoplasty "), which I hesitate to try Occasionally, however, when first operating on extensive cavitation, or when performing sequestrectomy, such a delay may be anticipated, and, instead of making an incision, a *wedge* of superficial tissue may be excised to allow later collapse to take place It must not be forgotten, however, that by far the greater number of cavities contract rapidly and heal quickly, and I use the word " occasionally " advisedly

OTHER CASES

This series has not included private cases or cases among the nurses Septic hands (except paronychia, which is no respecter of persons) are less common and show fewer complications in the professional than in the working classes Perhaps the hands of professional people are less exposed to trauma (though this is less so nowadays , domestic occupations are common to all) , but greater factors are the thinner horny layer, which allows small infections to swell, and earlier alarm at pain I have not seen a pulp space develop osteitis in this class of patient in three and a half years, and I have not seen a case take longer than sixteen days to heal

DELAY

The greatest single factor preventing further improvement in results is delay in attendance at the clinic Only 18% of these patients attended within three days of onset of symptoms Our records are by no means complete in this respect, but an attempt to find how much delay is due to the patient and how much to treatment, in general practice surgeries, works first aid posts, and in our own clinic, establishes that doctors or nurses are responsible for at least 16% of the delay Some propaganda has been made outside, and more will be, but only the 16% is likely to be affected by it I have noticed a high incidence of the " doctor (or nurse) made a nick " history in the osteitis cases, and blame the method mainly because it encourages further delay before seeking hospital treatment to see if the " nick " has done any good The increasing use of penicillin in practice has the same effect Undoubtedly many cases in general practice resolve successfully on penicillin therapy, but this may lead to longer delay in referring the ones that do not respond, and this is unfortunate

It would be absurd to demand the immediate attendance of every pricked finger end that has pain. Not only would the department be unable to deal with them, but it would lose the respect of the area Yet advice must be precise Any case suspected of early pulp space infection should have a kaolin poultice applied, the whole hand put at absolute rest, and one's favourite " big " dose of penicillin It must be seen again within twenty four hours If it is improved (and a reply from the patient to a question about pain is usually reliable evidence), treatment should be continued, and one should be guided by events If it is no better it should be referred to the clinic forthwith

DISCUSSION

These 438 cases (table II) are taken from a series of about 2700 septic hands seen in the clinic in three years The total number of non orthopædic non dermatological hand conditions seen in this time was a little over 13,000. The pulp space infection has been selected because it is the most important single condition demanding attention, but in such a condition, even with a comparatively large series, where incapacity for work can vary from three days to one hundred and thirty three days, it is almost impossible to draw any reliable conclusions from the figures alone The figures, though care has been taken, are only roughly reliable As an instance, the 3 cases of

osteitis in 1949 " seen within three days " were almost ertainly late cases 2 had a central sinus when first een at the clinic, and the 3rd discharged a sequestrum our days after the first attendance Cases of obvious defaulters have been omitted, though these include many who get a quick response to conservative treatment and do not come back to tell us so (We lose many splints and slings !) To include them would brighten the picture considerably but unjustifiably Those who do not attend for their official discharge after a reasonable course of treatment have been counted up to their last attendance One patient for whom, on his sixteenth day, a dry dressing had been prescribed for three days, next appeared on his thirty seventh day He was assessed on the full period, though he had probably been healed a fortnight earlier

With these sources of error—and they must occur in all clinics if a long enough period is reviewed—I cannot understand how a few days' difference in the results can be attributed to any particular alteration in details of treatment—even including the use of penicillin Moreover, the descent of a surgical team on a casualty department for a limited period of time, with the consequent renaissance of enthusiasm and supervision of dressing technique, will produce an improvement in results whatever the " object of the exercise "

I do think it significant, however, that there has been a progressive reduction in length of treatment for the non osteitis cases (from 23 days in 1947 to 17½ in 1949), and that no case of massive necrosis has occurred in the course of treatment since 1948 I attribute these improvements to a tendency to treat each case on its merits instead of all cases by a routine There is no doubt also that penicillin in the early cases, with an increased adoption of the conservative approach, has contributed , but we have tried intensive penicillin therapy for osteitis cases along the lines laid down by Bolton et al (1947), with less successful results All their cases were healed within eight weeks, but every few months we are defeated by an isolated case which jolts our averages far out of their prescribed orbits

The conservative treatment has a definite rôle, but it applies only to a minority of the cases in this area, and is fraught with danger to the inexperienced The vast majority of patients attend too late for it, and in these cases, particularly, I believe improvement can be obtained by the abandonment of classical incisions

I am still concerned about delay (often up to three weeks) in seeking treatment, and I aim at eliminating all cases of osteitis which cannot be directly attributed to this delay Until this delay is eliminated, there will always be a hard core of refractory cases

SUMMARY

The results published by various teaching clinics on the treatment of septic hands excite the admiration of surgeons elsewhere, but must be regarded as a goal rather than a standard for the country as a whole

The results obtained in three years in a provincial casualty department are reported, with particular reference to infection of the digital pulp space The average delay in seeking treatment is greater than that reported by other workers, and osteitis is a formidable problem Measures are recommended to reduce the incidence of osteitis of the phalanx resulting from pulp space infection

It is suspected that much osteitis is caused by too rigid adherence to classical incisions The latter is nevertheless recommended for *early* pulp space infections not responding within 24 hours to conservative treatment

One acknowledgment makes all others relatively unimportant it is to the casualty officers and to Sister E L Bolam and her staff, quite inadequate in numbers, miraculously adequate in effect They give over 40,000 services a year in a room 24 ft square In the rush of it all they yet find the extra moments necessary to give a septic hand that skilful attention which makes all the difference

ÆTIOLOGY OF CHRONIC GASTRIC ULCER

OBSERVATIONS ON THE BLOOD-SUPPLY OF THE HUMAN GASTRIC MUCOSA WITH A NOTE ON THE ARTERIOVENOUS SHUNT

F S A Doran
M.D Camb , F R C S

LATE SURGICAL CHIEF ASSISTANT, CHRISTIE HOSPITAL AND HOLT RADIUM INSTITUTE, MANCHESTER, AND CLINICAL DEMONSTRATOR IN ANATOMY, MANCHESTER UNIVERSITY

When, in the last century, Virchow advanced his vascular hypothesis to explain the formation of chronic peptic ulcers he regarded it as being of fundamental importance, although he did not consider it to be the only factor at work in this condition In his view, the essential feature in the production of these ulcers was a vascular infarction of part of the mucosa, due to thrombosis, arteriosclerosis, spasm, or embolic occlusion, the resulting area of necrosis being then digested by the acid gastric juice This idea derived some support from the demonstration by Reeves (1920) that in the lesser curvature of the stomach the submucous plexus was composed of very small arteries with few anastomoses, unlike those existing in the rest of the stomach, and that the branches of this plexus supplying the mucosa were arranged in a manner that predisposed to thrombosis In recent years, however, the importance of this concept of the cause of peptic ulceration has steadily diminished Now, overshadowed by the neurogenic and chemical hypotheses, it attracts little attention This decline in the status of Virchow's hypothesis is attributable not only to the increasing mass of evidence in favour of the neurological and chemical factors but also because it is closely linked with the idea that the ulceration is preceded by infarction

Much experimental work has been based upon this concept of an infarct, as McCann's (1929) review shows, but the results weakened rather than strengthened the idea A remarkable assortment of substances, including mycotic emboli and tobacco, have been injected into the blood vessels of the stomach in laboratory animals to produce infarction , but even when ulceration resulted all the lesions healed in about three weeks Moreover no firm support was produced from the various ligation experiments, or from those which sought to bring about areas of mucosal ischæmia by means of vascular spasm (McCann 1929) More damaging still was the demonstration by Mann and Bollman (1932) that the chronic peptic ulcers which result experimentally from the diversion of the duodenal contents into the terminal ileum (Mann and Williamson 1923), and which are identical with those occurring clinically, begin not as an infarct but as a saucer like depression on the surface of the mucosa Nevertheless a modified vascular hypothesis, freed from the concept of infarction, could still be of value in helping to explain the situation of a chronic peptic ulcer, particularly in the stomach, and the recent work of Barclay and Bentley (1949) is a step in this direction

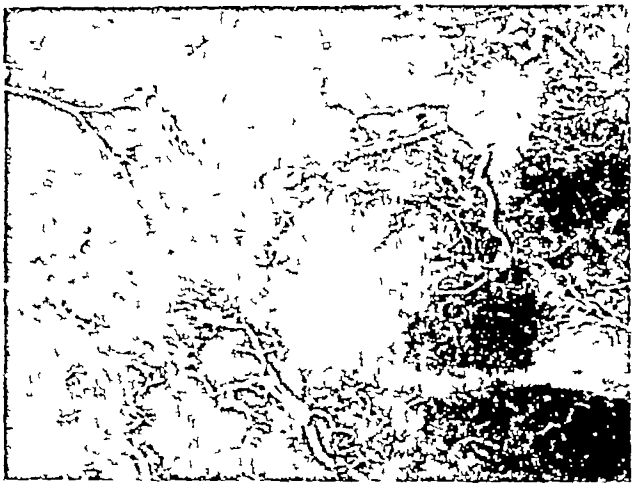

Fig 1—Microradiograph showing the vascular density of the mucosa on the lesser curvature of the stomach

METHOD

The technique employed in the present study was the radiological one devised by Barclay (1947) The contrast medium used to demonstrate the arterioles and finer vessels, with which this investigation is alone concerned, was a colloidal suspension of 10% silver iodide (Barclay and Bentley 1949) injected with a syringe through a hypodermic needle tied into a convenient artery, usually the right gastro epiploic, the small bore of such a needle being found to act as a convenient safeguard against the development of too great a pressure The mercury manometer and pressure chamber used in the preliminary trials were therefore discarded as being unnecessary

The material consisted of portions of sixteen stomachs removed during partial gastrectomy in the treatment of chronic peptic ulceration Ten were done under general and six under epidural anæsthesia In four instances the lesion was a gastric ulcer, the remainder being duodenal ulcers

The injection was always made as soon as possible after the specimen had been removed In most instances the delay was three or four hours, in two instances the injection was performed within an hour, and in a few the delay was twelve hours

To obtain adequate filling of the arterial system i found necessary not only to ligature all points of le along both curvatures but also to oversew the cut e the stomach from which leakage was otherwise ver

The injection was continued until a slight res was encountered Then the specimen was radiogr to confirm that the filling of the arterial systen satisfactory The next step was to slit the sto longitudinally down its anterior wall midway be the greater and lesser curvatures The specimen opened out flat and radiographed This second fil then examined with a magnifying glass, suitable were selected, the corresponding pieces were excised the stomach, and microradiographs were made of

Although in the preliminary trials an attempt was to wash all the blood out of the vessels with saline so before the contrast medium was injected, this ste not taken in any of the twelve specimens radiogr in this series

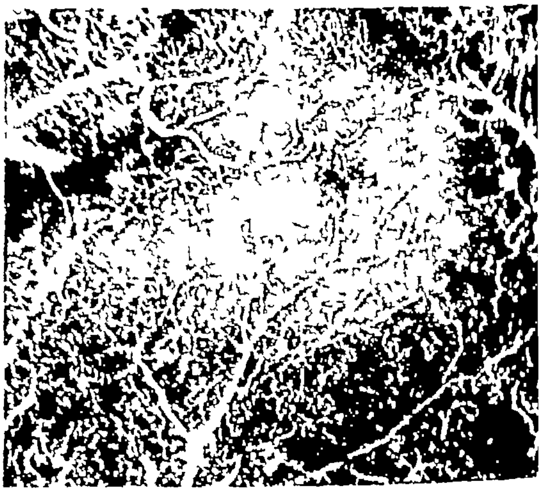

Fig 2—Microradiograph showing the vascular density of the mu the greater curvature of the stomach

The four specimens used to demonstrate the a venous shunt, however, were treated in a di manner, the technique of intravascular hæmat advocated by Grant (1930b) being used

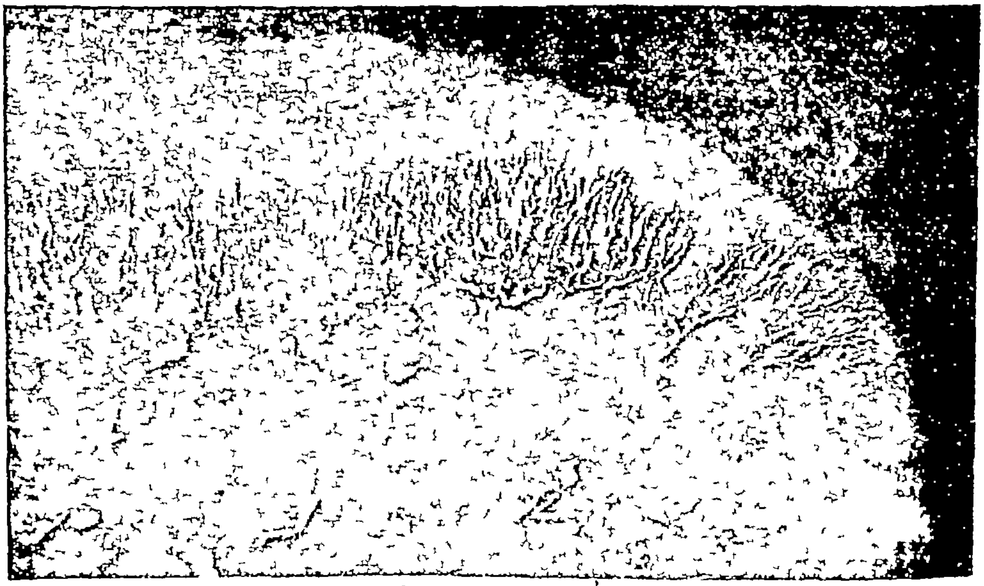

Fig 3—Microradiograph of vertical section 100 µ thick through edge of large chronic gastric ulcer showing vascular pattern

MUCOSAL BLOOD-S

The vessels whic ply the gastric m arise from a rich in the submucosa behaviour as they towards the sube lial layer of the mu and their relations the gastric glands, been-known for a dred years Th proved by Arnold' gram made in 184 reproduced by La (1931) A good de tion is given al Jonnesco and (1912) These acc are confirmed by present study

The vessels origin from the subm plexus penetrate muscularis mucosa immediately divid two main branch

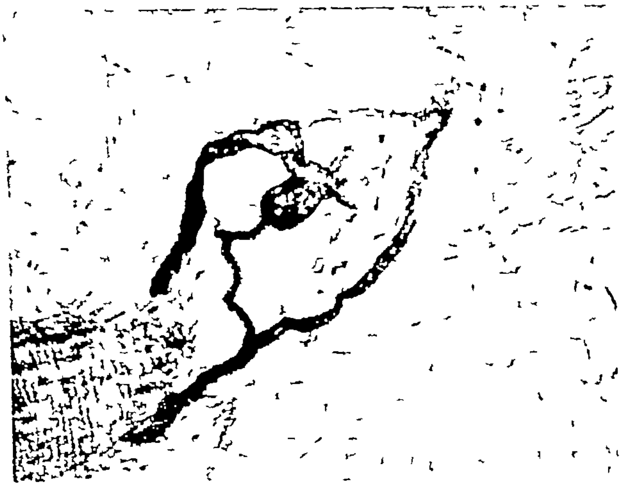

Fig 4—Histological section 100 μ thick showing an arteriovenous shunt with the characteristic sudden enlargement in lumen of the anastomotic channel (Intravascular hæmatoxylin)

right angles to the parent stem These branches run longitudinally parallel to the muscularis mucosa which they have just pierced The extremities of these branches anastomose with those springing from the neighbouring vessels of the same kind From this longitudinal arcade, lying just on the mucosal side of the muscularis mucosa numerous vertical arterioles arise which penetrate the thickness of the mucosa to reach the subepithelial layer These arterioles are of three types - (1) long straight vessels varying somewhat in calibre and without branches, (2) vessels showing one primary division, and (3) a short vertical stem which breaks up into a moderately complex series of arborisations

From the ends and sides of these arterioles numerous capillaries arise which anastomose with similar vessels from neighbouring arterioles to form a rich plexus throughout the whole thickness of the mucosa The system of vascular anastomoses which exists in the substance of the mucosa, as opposed to the intercommunicating vascular arcade lying on the muscularis mucosa, is composed of capillaries Anastomoses between the arterioles are not common, a point which has been emphasised by Latarjet (1931)

The relationship of these arterioles and capillaries to the tubular glands of the body of the stomach is a simple one The arterioles run parallel to, and in between, the glands Most of the glands, however, are supplied by two or three capillaries originating from the arterioles and placed in the reticular tissue connecting the glandular tubules together, these capillaries also run parallel to the glands and are interconnected by short channels at right angles to the long axis of the tubule

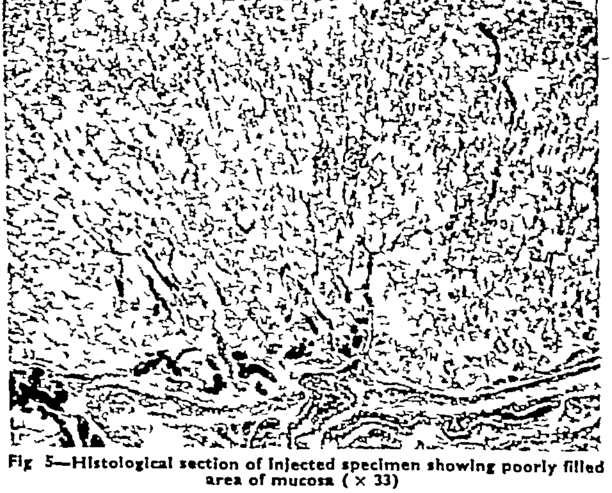

Fig 5—Histological section of injected specimen showing poorly filled area of mucosa (× 33)

DENSITY OF DISTRIBUTION OF BLOOD VESSELS SUPPLYING GASTRIC MUCOSA

Possibly the formation of a chronic gastric ulcer is due in part to the chemical action of the acid gastric juice upon a piece of mucosa whose total vascularity makes it unable to withstand that action Several specimens in the present series support this idea that the lesser curvature has fewer vessels per square inch of mucosal surface than has the greater curvature This point is illustrated by figs 1 and 2, which are microradiographs of mucosa from the lesser and greater curvatures respectively of a stomach resected because of a gastric ulcer In each case the mucosa has been dissected off the muscular coats and spread out flat upon an X-ray plate so that the vascular density in the same plane as the mucosal surface is shown This lower density is not evident in a section at right angles to the mucosal surface, even at the edge of a large gastric ulcer (fig 3) It is of particular interest to note that in cases of duodenal ulcer the vascular density of the lesser curvature tends to be the same as that of the greater

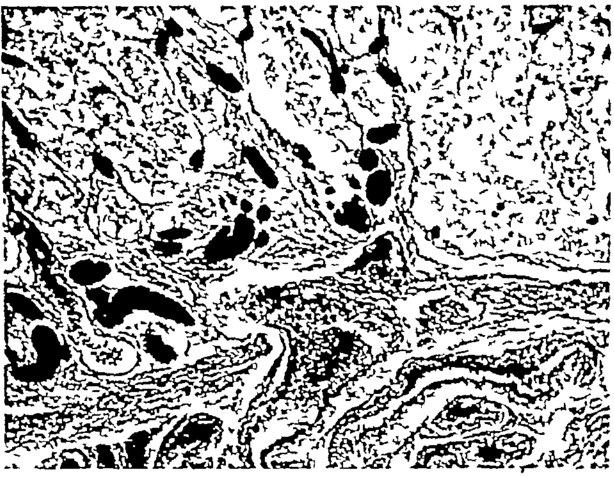

Fig 6—Histological section of the same area as in fig 5 under high power showing that the injection material has not been diverted into the vein passing through the muscularis mucosæ (× 78)

FACTORS INFLUENCING THE MUCOSAL BLOOD SUPPLY

RÔLE OF ARTERIOVENOUS SHUNT

If, in addition to a lower vascular density of the ulcer bearing area of the stomach, this region is exposed to the operation of other factors tending to diminish its blood supply, the vascular hypothesis would be strengthened further

It has been suggested (Barclay and Bentley 1949) that the blood supply of the gastric mucosa can be cut off completely by the opening of arteriovenous shunts in the submucosa, the ætiological significance of which has been noted by Alvarez (1949) He even suggested that the correct line of surgical treatment for chronic gastric ulceration would be the denervation of the shunts to prevent them from opening

The existence of an arteriovenous shunt was doubted for many years, even after they had been demonstrated histologically, as the historical reviews (Clark 1938, Boyd 1939) of the subject show Now they have been definitely established, and their presence proved in several organs and tissues They were first seen in vivo by Grant (1930b) Recently, however, they have been found in the stomach wall (De Busscher 1948, Barlow 1950), and an example from the present series is shown in fig 4

If the future treatment of chronic gastric ulceration is to be based upon the denervation of the shunts, the properties of their nervous control must be studied The view has been expressed (Barclay and Bentley 1949) that they are supplied by the sympathetic and opened by its stimulation This opinion resulted from an inference based on the observation that, if the gastric resection was performed under general anæsthesia, leaving the sympathetic pathway open to convey the efferent side of a reflex initiated in the abdominal parietes, the injection material did not enter the mucosa Conversely, if the efferent sympathetic path was blocked by a spinal anæsthetic, the injection medium passed freely into the mucosal vessels This observation, however, has not been confirmed by the present study, in which no definite correlation was found between the mucosal filling and the type of anæsthetic, as follows

Case no	*Mucosal filling*	*Anæsthetic*
1	Good	General
2	Poor	Epidural
3	Quite good	Epidural
4	Good	General
5	Good	General
6	Poor	General
7	Quite good	General
8	Moderate	General
9	Moderate	Epidural
10	Poor	General
11	Quite good	General
12	Moderate	General

The best mucosal filling was obtained in a specimen removed under general anæsthesia Moreover, although the shunt mechanism is known to be under powerful sympathetic control, it has been demonstrated by Grant (1930b) that sympathetic stimulation closes the shunts Another difficulty in the way of attributing mucosal filling defects to the opening of an arteriovenous shunt is Grant's (1930b) observation that, when the shunt opens, a reflux flow of blood to the periphery occurs distal to the opening of the anastomotic channel This is of importance, especially as regards the stomach, because its veins, being part of the portal system, are devoid of valves Some of the injection material might therefore be expected to pass through the shunt and backward up the veins into the mucosa This retrograde pathway could not be detected in a microradiogram It is, in fact, very difficult to differentiate between arterioles and venules even histologically Grant's (1930a) study of the factors determining the calibre of the small peripheral branches of the arterial tree make it more probable that these mucosal filling defects are due to local vascular spasm caused by direct pressure and the action of a product of tissue damage To resect a stomach without bringing these factors, whose effect is independent of the nervous system, into play in various degrees is unlikely Furthermore, technical artefacts are certain to occur If the filling defects were due to a shunt, the diverted injection material should be found in the appropriate veins, but, as figs 5 and 6 show, this evidence was not found

Lastly, the number of shunts needed to achieve an extensive diversion of blood from the mucosa would be large, unless they were of great size The present series, however, suggests that they are neither numerous nor large, and De Busscher's (1948) findings agree with this opinion Nor is there any evidence that they are confined to, or are more numerous in, the ulcer bearing area

CONCLUSIONS

The lower vascular density of the lesser curvature of the stomach is probably one of the factors responsible for the observed localisation of chronic gastric ulceration to this region

The ætiological significance which has been predicted for the arteriovenous shunt mechanism is premature

SUMMARY

The importance attached to the vascular component in the ætiology of chronic gastric ulcer has steadily diminished in recent years, and the reasons for this decline are given

The vascular hypothesis may still be of value if it can be shown that the ulcer bearing area contains certain peculiarities

The material studied, the radiological method used, and the contrast medium injected into the arterial tree are described

Microradiographs show the lower vascular density of the mucosa from the lesser curvature

The technical difficulties inherent in the method are discussed, and it is shown that deductions based on radiological filling defects are open to criticism

An example of an arteriovenous shunt in the stomach wall is given Its ability to divert the injection material from the mucosa is discussed

I wish to thank Prof G A G Mitchell for his help in the preparation of this paper, Prof J Morley, Mr R L Newell, Mr R L Holt, Mr G O Jolly, and Mr W A B Nicholson for an ample supply of specimens, Mr F L Newell and Mr K Pearson, for their highly skilled technical assistance and Mr H Gooding and Mr P Howarth for the photographs The expenses of the investigation were partially defrayed from a Medical Research Council departmental grant

THE ELECTROPHORETIC SERUM-PROTEIN PATTERN IN MALIGNANT MALNUTRITION

C. G. ANDERSON
Ph.D. Birm., Dip. Bact., A.R.I.C.
OF THE SERUM DEPARTMENT, SOUTH AFRICAN INSTITUTE FOR MEDICAL RESEARCH, JOHANNESBURG

The late A. ALTMANN
M.D. Berlin, M.D. Witwatersrand, L.R.C.P.E., D.T.M. & H.
OF THE DEPARTMENT OF PÆDIATRICS, BARAGWANATH NON-EUROPEAN HOSPITAL, JOHANNESBURG

WE report here the results of an electrophoretic examination of the sera of patients suffering from malignant malnutrition (kwashiorkor, infantile pellagra), taken at various stages from the beginning to the end of treatment and at various times after recovery. The work is part of a larger study of the clinical, histological, and biochemical aspects of malignant malnutrition which will be reported in due course. The anæmia involved has already been described by Altmann and Murray (1948).

METHODS

The blood samples were drawn from the fontanelle and allowed to clot. The serum was separated, and the specific gravity determined by the copper sulphate method. The protein content was calculated from the specific gravity, using the formula $P = 364\ (G_p - 1{\cdot}0060)$ where P is the amount of protein in grammes per 100 ml. of serum and G_p is the specific gravity, given by Hoch and Marrack (1945).

Serum samples were appropriately diluted in phosphate buffer, pH 7·5 and $\mu = 0{\cdot}1$, and dialysed against the same buffer solution until equilibrium (as determined by change in refractive index) was reached; 24–48 hours in the refrigerator at about 4°C was usually adequate. The electrophoresis runs were made in the Tiselius apparatus at 1°C with 10 mA at a potential gradient of approximately 4·5 V per cm. The photographic records were enlarged five times by projection, the curves traced, and the areas corresponding to the different components measured with a planimeter and the proportion of each component in the whole serum was calculated. The averages of values determined for both ascending and descending columns at two or three time intervals were used. The absolute amount of each component was calculated from the proportion and the known total protein content of the serum.

ELECTROPHORETIC COMPONENTS OF SERA FROM CASES OF MALIGNANT MALNUTRITION AND NUTRITIONAL ŒDEMA

* Nitrogen estimated by Kjeldahl method

RESULTS

The values obtained for sera from 13 cases of malignant malnutrition and from 9 cases of nutritional œdema are given in the table The "normal" values quoted are the mean of many such values given in the literature Lubschez (1948) found that the mean values given by electrophoresis of sera from normal children were about the same as those for adults, although the range was considerably greater

DISCUSSION

It can be seen that the serum protein value is low at the time of admission to hospital, as previously reported by Trowell (1944), Gillman and Gillman (1945), and Altmann (1948), and rises during the course of treatment on a diet with a high protein intake A normal total serum protein content is reached in three to four weeks, in which time clinical recovery also occurs The outstanding features of the protein pattern in malignant malnutrition are the low absolute and relative amounts of albumin compared with normal values, and the high absolute and relative amounts of γ globulin Even on admission to hospital when the total protein is at its lowest level the amount of γ globulin is almost always higher than normal As the normal serum protein level is restored both albumin and globulin rise Usually the amount of albumin in the serum at the time of clinical cure is somewhat below the normal average but the amount of γ globulin is almost invariably higher That this abnormal state may persist for some time is shown by case 9 On discharge as clinically cured this patient had 2 98 g of albumin, and 3 07 g of γ globulin, per 100 ml of serum On readmission to hospital six months later for follow up study, the values were 3 74 g and 2 27 g Twelve months after cure the albumin content was 4 09 g, and the γ globulin content 1 86 g, per 100 ml This patient's serum also showed, on all three occasions, the positive thymol turbidity and flocculation reaction often found in cases of malignant malnutrition during the recovery phase,[1] which is normally associated with an increase in the γ globulin content of the serum (Maclagan 1948, Wunderly and Wuhrmann 1947) He was clinically well and had been on a satisfactory diet in an institution during the twelve months since his original discharge from hospital The explanation and significance of these observations are not yet clear, particularly in relation to possible liver damage

The α globulin content of the sera is usually not far from normal and the same applies to β globulin, although here the tendency is for the value to be on the high side of the normal average

These findings are very much like those reported by Martin (1949) for sera from patients with progressive uncomplicated cirrhosis of the liver Here, too, the serum albumin is low and the γ globulin content very high, and accompanied by a strong thymol turbidity reaction In clinically cured cases of malignant malnutrition, however, liver biopsy specimens do not show signs of early cirrhosis

It will be seen from the table that there is no essential difference between the values found for the sera of patients suffering from nutritional œdema and those with the additional signs of the syndrome of malignant malnutrition This similarity affords support for the opinion of Altmann (1948) and of Waterlow (1948) that malignant malnutrition is primarily a result of protein deficiency and that the manifestations of vitamin deficiency are only incidental Further evidence of this is given by Hottinger et al (1948), who state that concentration camp inmates suffering from "hunger disease" had low serum albumin content, approximately normal α and β globulin contents, and high γ globulin content, the values being very similar to those found in the present work These workers go so far as to define "hunger disease" as "hypoalbuminæmia with dysglobulinæmia" The sera from their patients gave a positive Takata reaction, analogous to the thymol tests in this series

SUMMARY

The electrophoretic examination of sera, taken at various stages during treatment, from Bantu children suffering from malignant malnutrition or from nutritional œdema has shown that, although on admission to hospital the total serum protein content is much below normal values, the amount of γ globulin is both absolutely and relatively normal or higher than normal The albumin content is much reduced whilst the values for α and β globulins are about normal After clinical cure the albumin content of the serum is usually still below normal and the γ globulin considerably above normal The abnormal γ globulin content may persist for at least a year with the patient in good condition and on an adequate diet These findings are similar to those found in adults with "hunger disease" and therefore link malignant malnutrition to the hunger œdema of adults

UNIOVULAR TWINS SHOWING GROWTH DISPARITY DUE TO RENAL DWARFISM

M D Milne
M B, B Sc Manc, M R C P
CHIEF ASSISTANT, DEPARTMENT OF MEDICINE,
UNIVERSITY OF MANCHESTER

UNIOVULAR or so called "identical" twins are generally very similar both in appearance and size In a biometric study of more than five hundred members of twin pairs Stocks (1930) defined the differences in size to be expected in pairs of uniovular twins, he considered that "a difference in height exceeding the standard deviation of height appropriate to the age of the pair almost certainly excludes monozygotism"

Greater disparity in size is, however, occasionally encountered as a result of chronic disease or deformity in one of a monozygotic pair, but very few such cases are recorded, presumably because disease greatly influencing growth is likely to affect both twins simultaneously The case described here is of interest both because of the considerable disparity in growth and as an example of renal dwarfism of developmental ætiology

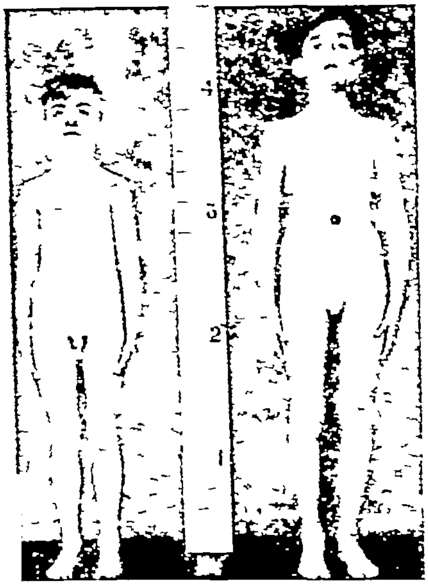
CASE RECORD

A boy, aged 13, was referred to the Manchester Royal Infirmary because of polydipsia, polyuria nocturnal enuresis, and dwarfism He was one of a family of five, three boys and two girls, and had a twin brother The parents and siblings all appeared healthy The patient had been considerably smaller than his twin brother at birth, their respective weights being 3 lb and $4^1/_2$ lb This disparity had persisted throughout childhood, and the patient had always been somewhat retarded in development He had always drunk an excessive quantity of fluid as long as the parents could remember, and had been late in gaining diurnal control of micturition Nocturnal control he had never attained, and he invariably wet the bed at night There seemed to be relatively little intellectual impairment, although he was poor at reading and writing, partly because of intermittent and often half time school attendance

---

[1] A paper describing the correlation of liver function and thymol tests is in preparation (Altmann and Bersohn)

On examination he was clearly dwarfed, his height being 50 in , the mean height for his age being $59^{1}/_{2}$ in (standard deviation 3 1 in.) His weight was correspondingly reduced to 50 lb , the mean weight for his age being 89 lb (S D $16^{1}/_{2}$ lb) There was however, no evidence of rickets or other deformity, and the dwarfing was perfectly symmetrical The heart and lungs were normal, and the blood pressure was within normal limits being 120/70 mm Hg No abnormal masses were palpable in the abdomen, there was no evidence of renal enlargement or vesical distension The urine was pale sp gr 1 010, and contained a moderate amount of albumin The average volume of urine voided in twenty four hours was about 1500 ml there was complete isosthenuria sp gr remaining at 1.010 despite restriction of fluids The average protein content of the urine Esbach) was 1 5 g per litre There was considerable retention of nitrogen. the blood urea level being 114 mg per 100 ml , the urea-clearance was only 13% of the average normal. The urine contained no pus cells or erythrocytes, but a few granular casts were present it was sterile on culture The serum-calcium was 9 mg the inorganic phosphorus 5 mg , the alkaline phosphatase 27 King Armstrong units and the alkali reserve 51 c cm CO_2 per 100 ml Radiography of the epiphyses showed no evidence of rachitic change, and radiography of the abdomen was normal there being no sign of urinary calculus or other abnormal opacity



ig 1—Patient (left) and uniovular twin (right) (Scale in ft.)

DIAGNOSIS

The diagnosis was clearly renal dwarfism due to chronic renal insufficiency without secondary hypertension This may cause the well known triad of dwarfism, renal rickets, and infantilism but in this case there was no evidence of rickets and the boy was too young to decide whether there would be secondary infantilism

This type of chronic renal failure in childhood is usually due either to chronic atrophic pyelonephritis or to chronic urinary obstruction, which may result from a congenital valve in the posterior urethra (Ellis and Evans 1933), rarer causes are latent glomerulonephritis and bilateral polycystic disease of the kidneys (Rule and Grollman 1944) On clinical grounds it was considered that chronic atrophic pyelonephritis was the most likely cause of the renal failure in this patient despite the lack of evidence of urinary infection Such cases of chronic pyelonephritis are often superimposed on some congenital anomaly of the upper urinary tract (Erb and Summerfeldt 1941) Unfortunately this cannot be demonstrated by intravenous pyelography in patients with gross reduction of renal function, because the kidneys do not concentrate the contrast medium sufficiently to give a satisfactory shadow Retrograde pyelography can be used, but it is a comparatively major procedure for an investigation which can only be regarded as of academic interest and can occasionally lead to a serious or even fatal urinary infection in such cases It was therefore regarded as unjustifiable in the present case, especially since relevant information was available from examination of the normal twin

COMPARISON OF THE TWINS

The patient's twin appeared to be a normal boy of 13 although somewhat smaller than the average His height was $56^{1}/_{4}$ in and weight 67 lb He had no polydipsia, polyuria, or nocturnal enuresis , his urine did not contain albumin, and the specific gravity of a morning specimen was 1 026 The blood urea was normal, being 26 mg per 100 ml

Despite the obvious difference in size it was considered that the twins were uniovular They were compared by the method described by Newman (1940) and, except for their unequal growth were found to be strikingly similar (figs 1 and 2) Their hair was of the same colour, texture and distribution , their eyebrows and eyelashes were almost exactly alike , their eyes were of the same colour , both twins had a congenital partial ptosis of the left eyelid , their ears were of the same shape , their teeth were much alike (but the patient's were more crowded because of his smaller jaws) , their palm and fingerprints showed considerable points of similarity , the two boys had a livedo reticularis of the legs of identical distribution , and the blood groups of both were O, R 2, MN, S negative, P positive, Lewis negative, and Lutheran negative

There therefore seems to be no reasonable doubt that the twins were uniovular It was consequently a reasonable assumption that if the patient had a congenital renal lesion it would also be present in his twin brother It was readily demonstrated in the twin brother by intravenous pyelography, a method inapplicable in the patient because of his renal insufficiency Dr E D Gray reported on the intravenous pyelogram (fig 3) as follows

> Neither kidney is enlarged and both appear to be excreting diodone normally Both kidneys have a pelvis which is largely extrarenal The left renal pelvis is considerably larger than the right The minor calices are smaller and more numerous than average, and except in the upper poles, arise directly from the pelvis It is difficult to define the pelvi ureteric junction on either side The somewhat unusual appearance of the upper urinary tract can be classed as a variant of the normal

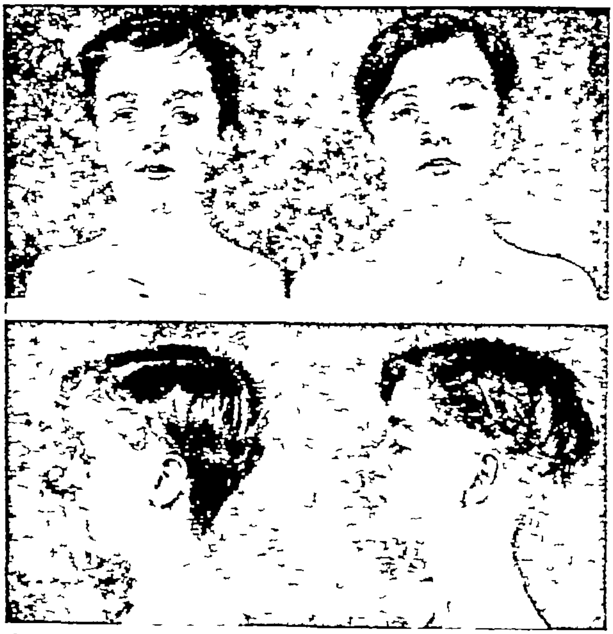


Fig 2—Full face and profile views of patient (left) and twin (right)

It is postulated that a chronic pyelonephritis has been superimposed on similar renal pelves in the patient, but no explanation is offered as to why this has happened in the patient and not in his twin

DISCUSSION

Few examples of such unequal growth in uniovular twins are recorded Siemens (1927) described female uniovular twins very different in height owing to scoliosis in one of them A similar case of kyphoscoliosis in one of male uniovular twins is described by Lehmann (1937) Lewis (1936) described a case of much disparity due to gigantism and acromegaly in one of uniovular twins An interesting example in Japanese male uniovular twins is recorded by Komai and Fukuoka (1934)

One of the twins developed polydipsia, polyuria, and dwarfism at the age of 6 years This was diagnosed as due to diabetes insipidus, but unfortunately the medical details are inadequately described The only evidence given in favour of the diagnosis is a disparity in size between their sellæ turcicæ, but as the smaller sella turcica was in the smaller twin this evidence can hardly be regarded as relevant A diagnosis of diabetes insipidus would not now be accepted without either evidence of satisfactory response to treatment with pituitary extract or a negative response to the intravenous hypertonic saline test described by Hickey and Hare (1944) Neither of these criteria was applied in this case Nor does diabetes insipidus in childhood lead to dwarfing unless it is secondary to cerebral tumour, xanthomatosis, or diencephalic encephalitis (Warkany and Mitchell 1939) No evidence was given of any of these conditions in the affected twin No tests of renal function seem to have been made, and in fact there is nothing in the published description against a hypothesis that the true diagnosis was renal dwarfism as in the present case

The growth disparities recorded in these cases are summarised in the accompanying table

Many cases of renal rickets and dwarfism, or lesions likely to cause this, have previously been described in siblings The cases published before 1930 have been reviewed by Mitchell (1930), who lists 11 instances of renal dwarfism or rickets in which more than one member of the family was affected Davidsohn and Newberger (1933) described twins, presumably uniovular, who died on the seventeenth and nineteenth days of life from uræmia due to congenital valves in the posterior urethra

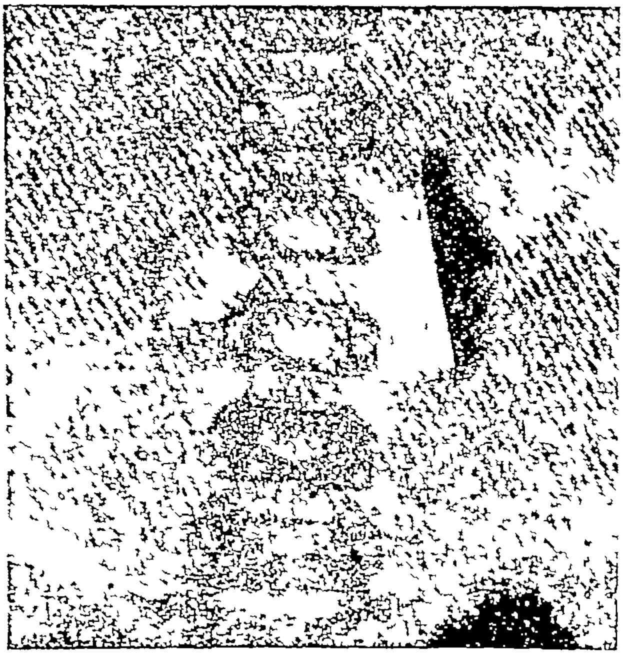

Fig 3—Intravenous pyelogram of patient's twin brother

Reference	Diagnosis	Sex	Age (years)	Height (cm)		S D appropriate to age (cm)	Growth disparity as multiple of S.D.
				Of shorter twin	Of normal twin		
Siemens (1927)	Scoliosis	F	16	142·0	154·0	5·75	2·1 × S.D.
Lehmann (1937)	Kyphoscoliosis	M	14	119·1	149·3	8·50	3·6 × S.D.
Lewis (1936)	Gigantism and acromegaly	M	46	194·3	172·7	6·50	3·3 × S.D.
Komai and Fukuoka (1934)	Claimed to be diabetes insipidus	M	15	140·0	154·8	8·20	1·8 × S.D.
Present case	Renal dwarfism	M	13	127·0	143·0	7·96	2·0 × S.D.

Weill Hallé et al (1939) described a brother and sister both of whom were renal dwarfs Graham and Hutchison (1941) recorded a family in which certainly 3, and possibly 4, of 8 siblings were renal dwarfs Of these, 2 were twins, but they were clearly dizygotic, for they were of unlike sex Danis and Rossen (1941) recorded renal dwarfism and rickets in a brother and sister Mackay (1945) described a family in which 5 siblings had congenital lesions of the kidneys or of the ureters

The importance of congenital lesions of the upper urinary tract causing pyelonephritis is emphasised by Erb and Summerfeldt (1941), who found, in 1148 consecutive necropsies on children, that 4·4% of such congenital anomalies were associated with pyuria during life. Hawthorne (1941) describes how such lesions lead to urinary infection which often persists despite therapy Of 95 cases of urinary infection in childhood, 60% proved resistant to treatment owing to a congenital lesion demonstrable by intravenous pyelography In a statistical review of 471 cases of congenital anomalies of the kidney and ureter Smith and Orkin (1945) stated that there is often predisposition to poor function and stasis, with retention and subsequent infection Of this large series 10 seem to be anatomically similar in type to the present case Although this type of pelvis is classed radiologically as a variant of the normal, it would appear to be an undesirable variant in view of possible complicating infection

SUMMARY

A case of renal dwarfism is described together with an apparently normal uniovular twin brother in whom, however, intravenous pyelography demonstrated unusual renal pelves

The published cases of unequal growth in uniovular twins, and the familial occurrence of renal dwarfism and rickets, are briefly reviewed

I am grateful to Prof Robert Platt for permission to publish this case, to Dr E D Gray for the radiological investigation and report, to the Regional Transfusion Service, North West Region, for determination of the blood groups, and to the departments of clinical pathology and of medical photography, Manchester Royal Infirmary, for the pathological investigations and the illustrations respectively

ADDENDUM

Since this paper was written, the following similar case has been studied

A married woman, aged 22, was admitted to the Manchester Royal Infirmary under Dr J F Wilkinson for low back pain, polyuria with nocturnal frequency of micturition and polydipsia, and anæmia She had 3 brothers and 4 sisters, one of the sisters being her twin, all these were perfectly healthy She had had nocturnal and diurnal polyuria and consequent frequency of micturition for as long as she could remember, she had always had to drink more than the average both by day and by night In June 1949 she had become pregnant, and the doctor found that she was anæmic and she had not responded to adequate iron therapy Her pregnancy had terminated at the fourth month in a miscarriage associated with considerable blood loss Since the pregnancy the patient had become breathless on exertion and had frequent attacks of palpitations over the same period she had had chronic aching pain over the sacrum which was made worse by exercise For the last two years she had noticed progressive blurring of vision

On examination she was small but normally proportioned height 55¾ in. weight 84 lb She was obviously anæmic and her mucosæ and skin were rather dry Her heart was enlarged towards the left side the apex beat being 1 in outside the mid-clavicular line her blood pressure was normal 115/75 mm Hg Movement of the lumbar spine was somewhat limited, with pain on extension and tenderness on percussion the urine showed constant albuminuria bilateral radiate cataracts typical of chronic hypocalcæmia were present in both eyes there was, however, no evidence of latent tetany The blood had a hæmoglobin content of 50% of the average normal (7 4 g per 100 ml), the colour index being 0 83 total and differential white cell counts were normal The average protein content of the urine (Esbach) was 0·75 g per litre there was complete isosthenuria, sp gr being constantly 1 010, some red cells and pus cells were present on microscopy The blood urea level was 190 mg per 100 ml , and the urea clearance 10% of the average normal The serum-calcium level was 6 5 mg per 100 ml serum inorganic phosphorus 7 9 mg per 100 ml , serum alkaline phosphatase 32 King Armstrong units and the alkali reserve 43 vol CO_2 per 100 ml Electrocardiography showed prolongation of the Q–T interval owing to the hypocalcæmia Radiography showed that the epiphyses were normally closed but there was evidence of renal osteodystrophy in that pseudo fractures were present in the right 10th and 11th ribs Radiography of the abdomen revealed no evidence of abnormal calcification or renal calculi In summary this was a case of normotensive uræmia with chronic hypocalcæmia and consequent formation of cataracts but not showing any evidence of tetany because of the severe acidosis due to the renal failure The patient had a refractory anæmia and an early osteodystrophy both of which were secondary to the uræmia

Her twin sister was 2¾ in. taller than the patient and appeared perfectly healthy, she was not anæmic her urine was of normal specific gravity and contained no protein, and her blood urea level was 20 mg per 100 ml. She was however, in the later stages of pregnancy, and therefore intravenous pyelography has had to be delayed until after her future delivery

The twins were considered to be uniovular by the method described above, this was confirmed by the blood groups, these being identical as follows O, cDe/cDe M, S negative, P positive, Lewis a-negative b positive Lutheran a negative, and Duffy a negative

This is, therefore, a further example of growth disparity in uniovular twins secondary to chronic renal failure in one of the pair , the disparity amounted to 7 cm , which is only just above the standard deviation of height appropriate to age and sex—i e 5 95 cm (equivalent to 1 18 × S.D)—and therefore only just outside the maximum variation in normal uniovular twins as defined by Stocks (1930)

I am grateful to Dr J F Wilkinson for permission to publish this case

TESTS of glucose tolerance are designed to reveal a failure to maintain the blood sugar level within normal limits under the stress of a carbohydrate load The test may show normal or reduced tolerance The latter is often termed " diabetic " despite the common finding of such a reduction of tolerance in many conditions other than diabetes mellitus This diabetic type of glucose tolerance curve has been described as high and spread,' although it is recognised that the degree of hyperglycæmia attained is of no significance (Spence 1920, MacLean and de Wesselow 1920, Mosenthal 1947a) Reduced sugar tolerance is shown by protracted hyperglycæmia It is considered that two hours after 50 g of glucose has been taken by mouth the venous blood sugar level should normally fall to below 120 mg per 100 ml and that blood sugar levels above this indicate a reduction of glucose tolerance (Hale White and Payne 1926, Laugmer and Dewees 1942, Duncan 1947, Mosenthal 1925 and 1947b) Moyer and Womack (1950) allow 125 mg per 100 ml as the upper limit of normal.

As alternatives to complete tolerance tests and to estimation of the 2 hour blood sugar level * certain blood-sugar levels for both fasting and non fasting states have been suggested as reliable indications of reduced sugar tolerance Most workers give about the same figure for the upper limit of the normal range of the blood sugar level in the fasting state Hale White and Payne (1926), Mosenthal (1947a and b), and Moyer and Womack (1950) regard 120 mg per 100 ml. as the highest acceptable figure, whereas Joslin (1946) and Lawrence (1950) regard any fasting blood sugar level above 130 mg per 100 ml as indicating diabetes mellitus In the non-fasting state diabetes may be diagnosed according to Joslin (1946), if the venous blood-sugar level exceeds 170 mg per 100 ml or the capillary blood sugar level is above 200 mg per 100 ml. in the presence of glycosuria Lawrence (1947, 1950) expresses a similar opinion , but Moyer and Womack (1950), investigating 103 normal persons, could not define any postprandial blood sugar level having this significance

With a few exceptions, these standards of reduced sugar tolerance seem to have been suggested as a result of extensive experience over many years They are critically examined here with the 2 hour blood sugar level as the index of glucose tolerance

INVESTIGATION

In the years 1940–49 inclusive 1582 patients were submitted to a glucose tolerance test of the standard type One dose of glucose 50 g was given by mouth after an overnight fast, the venous blood sugar level was estimated at half-hourly intervals for two hours by Benedict s (1928) method until late in 1948, and subsequently by the method of Folin and Wu (1920) and Folin (1928)

In these 1582 tests a fasting blood sugar level of at least 120 mg per ml was found in 431 cases and a 2 hour blood-sugar level of at least 120 mg per 100 ml. in 424 of these 431 (table I) Therefore, if a fasting blood sugar level above 120 mg per 100 ml. had been taken to denote that a diabetic type of tolerance curve would follow, 7 (1 6%) persons would have been diagnosed incorrectly as intolerant of glucose On the other hand, a considerable number of cases of intolerance would have been missed, for, though 1151 cases showed a fasting blood sugar level under 120 mg per 100 ml, only 982 had a 2 hour level under 120 mg per 100 ml Therefore 169 (26 8%) of the curves of diabetic type would have escaped detection

---

* 1½ and 2 hour blood sugar levels mean the venous blood-sugar levels at these times after the administration of glucose 50 g by mouth.

When the fasting blood sugar level was 130 mg per 100 ml or higher, the 2-hour blood sugar level was invariably at least 120 mg per 100 ml Of the 593 curves of diabetic type only 378 showed a fasting level of 130 mg per 100 ml or higher, hence the remaining 215 (36 3%) would have been wrongly forecast as showing normal tolerance

The height of the curve produced after the oral administration of glucose had, in this series, no significance Table II shows clearly that blood sugar levels of 170 mg per 100 ml or higher at 1 hour do not invariably denote a loss of tolerance to glucose 607 curves showed a 1 hour level greater than 169 mg per 100 ml 75 (12 35%) of these did not show any reduction of glucose tolerance, since their 2 hour blood sugar level was less than 120 mg per 100 ml 3 patients with a 1 hour hyperglycæmia in excess of 230 mg per 100 ml showed normal glucose tolerance, since the blood sugar level fell to below 120 mg per 100 ml in the course of the second hour of the test (Beckwith 1947) There were 52 patients (8 8%) with reduced tolerance whose blood sugar level did not reach 170 mg per 100 ml at 1 hour, these would have been incorrectly classified as normal from the 1 hour blood sugar level alone Similar, though smaller, errors were found when the 1¹/ hour blood sugar levels were examined (table III) 512 curves showed a 1¹/₂ hour level higher than 169 mg per 100 ml, of these, 16 (3 1%) had fallen below 120 mg per 100 ml in the following half hour Adoption of 170 mg per 100 ml as the critical level at 1¹/₂ hours would also have excluded 47 curves showing reduced tolerance—an error of 3 2% in 1469 tests

TABLE I—TWO HOUR BLOOD-SUGAR LEVELS COMPARED WITH FASTING LEVELS

Fasting blood sugar level (mg per 100 ml)	No of cases	2 hour blood-sugar level (mg per 100 ml)			
		0–119	120–129	130–139	>140
0–119	1151	982	44	27	98
120–129	53	7	1	3	42
130–139	28	0	1	0	27
>140	350	0	0	0	350
Total	1582	989	46	30	517

DISCUSSION

As a result of the examination of 2 hour blood sugar levels in a standard glucose tolerance test reduced tolerance may be revealed No further information may be gleaned from the test In diabetes mellitus there is no relation between the blood sugar levels during a tolerance test and the severity of the diabetes (as judged by daily requirements of insulin) The so called renal sugar threshold can be assessed only with great inaccuracy from the results of an investigation which commonly uses venous blood and makes no allowance for variation of glomerular filtration rate in the kidney (Mirsky and Nelson 1943) Complete standard tolerance tests cannot be justified, since the only information obtained from the five blood and three urine examinations of the test can be found equally well by estimation of a single 2 hour blood sugar level

TABLE II—TWO HOUR BLOOD SUGAR LEVELS COMPARED WITH ONE HOUR LEVELS

1 hour blood sugar level (mg per 100 ml)	No of cases	2 hour blood sugar level (mg per 100 ml)	
		0–119	>120
0–169	954	902	52
170–179	36	23	13
180–189	33	19	14
190–199	47	16	31
200–209	41	7	34
210–219	29	3	26
220–229	31	4	27
>230	390	3	387
Total	1561	977	584

TABLE III—TWO HOUR BLOOD SUGAR LEVELS COMPARED WITH 1¹/₂ HOUR LEVELS

1¹/₂ hour blood sugar level (mg per 100 ml)	No of cases	2 hour blood sugar level (mg per 100 ml)	
		0–119	>120
0–169	957	910	47
170–179	25	9	16
180–189	34	2	32
190–199	20	1	19
200–209	26	2	24
210–219	23	0	23
220–229	30	1	29
>230	354	1	353
Total	1469	926	543

This analysis shows that, if the 2 hour blood sugar level is the index of glucose tolerance, errors occur if fasting or postcibal blood sugar levels are taken in place of the 2 hour level Normal people are included in the group showing reduced tolerance, no matter which criterion is adopted, apart from a fasting level exceeding 130 mg per 100 ml, though Gray (1923) found that 2 3% of 431 normal people showed a fasting blood sugar level higher than this He did not, however, indicate whether or not the 2 hour level in these cases signified reduced tolerance, and distinguished only that these people had not got clinical diabetes mellitus

TABLE IV—ERRORS ARISING WITH DIFFERENT CRITERIA

Blood sugar level used as criterion (mg per 100 ml)	No of cases	No of normal curves wrongly included	No of curves of diabetic type wrongly excluded
Fasting >120	431	7 (*1 6%*)	169 (*26 8%*)
Fasting >130	378	Nil	215 (*36 3%*)
1 hour >170	607	75 (*12 3%*)	52 (*8 8%*)
1 hour >200	401	17 (*3 46%*)	110 (*15 5%*)
1¹/₂ hour >170	512	16 (*3 1%*)	47 (*8%*)
1¹/₂ hour >200	433	4 (*0 9%*)	114 (*19 %*)

Relying on the fasting and postcibal blood sugar levels as evidence of reduced tolerance instead of the 2 hour blood sugar levels would have caused an omission of cases which did show, in fact, reduced tolerance in their 2 hour levels (table IV) If the fasting blood sugar levels alone had been taken as an index of reduced sugar tolerance, curves of diabetic type, sufficient in number to invalidate the fasting blood sugar level as a diagnostic aid, would have escaped detection Though a fasting level above 130 mg per 100 ml confirms a reduction of sugar tolerance, a normal fasting blood sugar level is of no significance Similarly, table IV shows that adoption of the 1 hour or the 1¹/ hour blood sugar level as a criterion of reduced tolerance will lead to the exclusion of a considerable number of curves of diabetic type

It is concluded that there are no sensitive specific methods of detecting reduced tolerance other than estimation of the 2 hour blood-sugar level

SUMMARY

1582 standard glucose tolerance tests have been analysed

If reduced tolerance of sugar is indicated by a venous blood sugar level higher than 120 mg per 100 ml 2 hours after taking glucose 50 g by mouth, 593 results in this series showed reduced tolerance

The blood sugar levels both fasting and postcibal, suggested as being significant of reduced sugar tolerance, are unreliable

I wish to thank Prof E C Dodds, F.R.S., for his advice and for permission to report results obtained in the S.A Courtauld Institute of Biochemistry, and Prof A Kekwick and Dr Robert Semple for their advice and criticism in the preparation of this paper

DUODENAL INTUBATION WITH MAGNET-TIPPED TUBES

A H JAMES
M.A., D.M. Oxfd M.R.C.P
ASSISTANT TO THE MEDICAL UNIT, ST MARY'S HOSPITAL, LONDON

INTUBATION of the duodenum, undertaken for diagnosis, treatment, or research, is often difficult Sometimes a tube passed into the stomach and pushed further enters the duodenum at once, more often it becomes coiled in the stomach, the tip being found usually at the pylorus or in the gastric fundus, partial withdrawal and replacement may or may not overcome the hindrance

Various procedures are used to assist passage through the pylorus, the most usual being to lay the patient on his right side and introduce the tube extremely slowly Delay results mainly from ignorance about what is happening to the tube tip, so that manœuvres are often misdirected, for example, a tube coiled in the fundus rarely finds its way into the duodenum however long the patient lies on his side At present this can only be overcome by using radiology, the progress of the tube being watched on the fluoroscopic screen or by means of serial films In practice such methods have many disadvantages if the procedure is lengthy, as it often is it hinders the work of busy radiological departments, if the screen is used the work has to be done in the dark, and the possibility of overdosage with X rays makes it necessary to hurry These difficulties are magnified when the patient is a small child, and very ill patients cannot be taken to the X-ray apparatus

In the course of research requiring duodenal intubation we have developed a method of locating the tube tip without the help of X rays, and have found this of practical value with both adults and children A small permanent magnet is incorporated into the tip of the tube, and its position within the abdomen found by detecting its magnetic field with a small compass needle Magnets of a size which can be used are detectable at a range of about 3$^{1}/_{2}$ in and a compass pressed on the abdomen can be brought within this distance of most parts of the stomach and duodenum

CONSTRUCTION

To make sufficiently powerful magnets one of the highly magnetisable nickel-cobalt aluminium alloys must be used in this work magnets were made of 'Ticonal' (Mullard Electronic Products Ltd) This alloy cannot be machined and has to be ground to suitable size and shape on a grindstone For use in adults the magnet should be cylindrical, 2 5 cm long and 6 mm in diameter, and tapered slightly at each end. For children the diameter should be 4 mm and the length 2 cm, or less for small infants The magnet is inserted into suitable rubber tubing (no 3 I R) and the end closed by dipping into crude 'Latex,' which, when dried, makes a satisfactory rounded end Holes are cut as required A plotting compass, measuring $^{3}/_{4}$ in in diameter and $^{1}/_{4}$ in in depth, is used

METHOD

When the tube tip is lying horizontally and the compass is placed over it, the needle oscillates more rapidly than it does in the earth's field, and aligns itself in the axis of the tube, one end or other will always point in the direction of the tube tip, and which end does this must be discovered by trial before the tube is passed In this way the orientation as well as the position of the tube tip in the stomach can be determined. If the magnet is "end on" below the compass, the needle will be seen to dip, and according to which end dips it can be decided whether the tube tip is pointing towards or away from the compass A little practice with a compass and magnet will make these points clear Sometimes the polarity of the compass needle becomes reversed during the intubation, under the influence of the strong field of the tube magnet, this causes the needle to point in the opposite direction relative to the tube It is usually obvious when this has happened, and it can be confirmed by a reference magnet, or by observing the orientation in the earth's field.

For duodenal intubation, the tube is passed into the stomach and then sought by pressing the compass on to the abdomen with the patient lying flat The compass must be held horizontally so that the needle can swing freely When it comes near the tube-tip the needle, previously swinging slowly in the earth's field, is seen to swing much more rapidly, and to point in a new direction, the place at which it swings most rapidly is the best guide to the position of the tube

Ideally the tip is found first in the mid epigastrium, pointing transversely to the right, and very superficially as judged by the rapidity of the oscillations When the tube is pushed further the tip is next found slightly above and to the right of the previous position, and pointing away from the compass—that is, backwards through the pyloric canal Finally when it enters the duodenum the tip is found at the outer border of the right rectus, pointing downwards, and much less superficially When this sequence has been observed the tube is almost certainly in the duodenum Often only the first and last positions are seen When the tip is obstructed in the fundus of the stomach it is less easy to localise exactly, but a magnetic field can be detected below the left costal margin or outside the left lower chest In children the findings are similar, the shorter distances in the child compensating for the smaller size, and therefore slighter power, of the magnet

RESULTS IN ADULTS

Duodenal intubation has been attempted with a magnet tipped tube in 17 adults When the tube was thought to have entered the duodenum, as judged by the compass, a radiograph was taken In 14 instances the tube was in fact in the duodenum, and in the remaining 3 it was in the pyloric antrum The compass thus proved correct in 82 5% of cases, and mistakes, naturally more liable to be made with fat patients, became less common with practice None of these patients had distended abdomens from intestinal obstruction, in such cases deep palpation with a compass is more difficult, but at the crucial point—namely, the pylorus—the tube tip overlies the spine and is therefore more easily approached With such patients a larger magnet would have a decided advantage

A magnetic tip is also of value in tubes used for gastric aspiration, particularly where, as in research, it is necessary to be certain that the fluid so obtained is really of gastric origin

INTUBATION IN INFANTS AND CHILDREN

Duodenal intubation of children is necessary for the certain diagnosis of fibrocystic disease of the pancreas, but often has to be abandoned after attempts which may last several hours have ended in failure The magnet tipped tube, enabling the work to be done in the ward, in daylight and at leisure, while providing constant information about the progress of the tube, has greatly increased the chances of success and reduced the time in which it can be achieved

The attempt was made in 21 children whose ages ranged from one month to six years, 8 being one year old or less In 20 the duodenum was reached (X ray confirmation being obtained in each instance), although in 1 case the tube was regurgitated before a satisfactory sample could be obtained, the remaining child, a boy aged 3 resisted so strongly that the attempt had to be abandoned Most samples were got in 15–45 minutes, one took 2 hours The juice was allowed to drip out without the aid of suction

Three procedures were found of the greatest assistance

1 The tube is more easily swallowed and controlled if it can be passed through the nose In 8 cases where it was not possible to do this owing to buckling of the tube, success was achieved with the aid of a piece of copper wire passed in through one of the holes to rest on the back of the magnet By this means it was possible to push the tube through the nose, and the wire was then withdrawn

2 When the tube becomes stuck repeatedly in the fundus of the stomach, it should be withdrawn into the œsophagus and replaced with the child lying face downwards

3 When the tube is in the pyloric antrum and pointing to the right, gentle pushing at the nose combined with intermittent pressure on the epigastrium, has often caused it to enter the duodenum without delay

In palpating a child with a compass it is particularly important to keep the compass level, when the child is crying, reliance can be placed on the behaviour of the compass only during the momentary relaxation accompanying inspiration

CONTROL OF INTESTINAL TUBES WITH A MAGNET

Various workers have tried to pull a tube through the pylorus with a magnet Mayer (1944) inserted a small magnet made of 'Alnico,' an alloy similar to ticonal, into the tip of a Miller Abbott tube, using an electromagnet placed on the right chest wall, he claimed that he was always able to pull the tube into the duodenum under fluoroscopic guidance At the start of this investigation it was hoped that the magnet tipped tubes would have the double advantage that they could be moved with a magnet outside the body as well as detected with a compass A ticonal magnet was made, of the largest size that could be conveniently handled —such a magnet being more powerful than an electro magnet worked by any supply of direct current likely to be available While this magnet could exert a pull on the tube of 100 g at a range of 0 5 cm, at 10 cm the pull was only 6–8 g, and the distance from the pylorus to the lateral chest wall is usually greater than this In practice there was never a convincing instance of a tube having entered the duodenum more rapidly with the magnet's help than without It was often possible to bring the tube out of the fundus and into the pyloric antrum, especially in children, but this can be done by more simple methods, such as that described above For these reasons magnet tipped tubes are of value only for use in conjunction with a compass

My thanks are due to the staffs of this hospital, of Princess Louise Hospital, Kensington, and of the Queen Elizabeth Hospital, Hackney Road, for permission to make observations on patients under their care, and especially to Dr W F Young for assistance with many of the intubations, and to Dr E. Rohan Williams and the staffs of the radiological departments of the above hospitals for their kind help

PROCAINE WITH HYALURONIDASE AS LOCAL ANÆSTHETIC

J N THORPE
M.B, Edin
ANÆSTHETIC REGISTRAR, UPTON HOSPITAL, SLOUGH BUCKS

FOR the reduction of Colles's fracture and similar injuries, the anæsthetic which is probably most often employed is nitrous oxide This, however, has several drawbacks Its anæsthetic properties are so slight that it is always given with a very small concentration of oxygen, which may be dangerous, particularly where the patient—like so many with Colles's fracture—is elderly and has cardiovascular disease In the young fit adult it is even harder to obtain satisfactory anæsthesia with nitrous oxide, and impossible to obtain adequate muscular relaxation Postoperative vomiting with its attendant risk of aspiration—slight though this may be—is not uncommon with nitrous oxide if the period of anæsthesia is prolonged, and when radiography does not show proper reduction of the fracture, the patient has to have another anæsthetic for correction of the deformity

If general anæsthesia is required, a quick acting barbiturate is preferable (1) *for the patient* because it is more pleasant than nitrous oxide and does not involve anoxia, (2) *for the anæsthetist* because quiet anæsthesia is rapidly and simply achieved, and (3) *for the surgeon* because the patient is immobile with muscles relaxed Its chief disadvantage is that the patient requires a bed and nursing supervision for some time after administration, either or both of which are difficult to provide in a busy and short staffed outpatient department

Brachial plexus block has been used for the reduction of Colles's fracture, but it is time consuming, not without danger, and, in inexpert hands at any rate, often fails.

The anæsthetic of choice in the treatment of this condition appears to be local infiltration anæsthesia But this method, though described in most of the orthopædic textbooks, is not widely practised, because satisfactory analgesia is not attained until the injected anæsthetic agent has diffused into the tissues surrounding the fracture site, which may take a quarter of an hour or more Even then, if diffusion has been insufficient—and this is not uncommon—some pain is experienced during the subsequent manipulation For these reasons most surgeons tend to regard local infiltration analgesia as a last resort where general anæsthesia cannot be used

A modification of this technique[1] has recently been tried at the Upton Hospital with promising results Before injection the local anæsthetic agent (for Colles's fracture 20 ml of 1% procaine) is mixed with 1000 "Benger units" of hyaluronidase ('Hyalase'), which promotes diffusion of injected substances Two injections are made the bulk of the solution is put directly into the fracture hæmatoma from the extensor aspect of the forearm, and 2–3 ml is infiltrated around the ulnar styloid process The anæsthetic solution diffuses rapidly all round the injured area and the fracture can be manipulated as soon as the needle is withdrawn The patient, being ambulant, can at once walk unaided to the X ray department, and, if reduction is found to be incomplete, further manipulation is possible straight away

---

[1] Kirby C K Eckenhoff J E Looby J P *Surgery* 1949 25 101 Moore D C *Anesthesiology* 1950, 11 464

To date, this technique has been used in 22 cases of Colles's fracture and 4 cases of Pott's fracture (using 40 ml of 1% procaine for the latter) Though the series is very small, we have been struck by the rapidity with which analgesia is achieved and by the fact that it has always been complete Despite the rapid absorption of the anæsthetic, the fracture area remains pain free for well over an hour in one of the cases of Pott's fracture, three manipulations were required over a period of $1^1/_4$ hours and no pain was experienced during that time

I should like to express my thanks to Mr G P Arden, accident and orthopædic surgeon, for his interest and advice, and to Mr I J Gordon the resident surgical officer, who performed most of the manipulations

A CASE OF
CONGENITAL AFIBRINOGENÆMIA

A I D PRENTICE
M C M B Camb
ASSISTANT PATHOLOGIST,
ESSEX COUNTY HOSPITAL, COLCHESTER

ONE of the causes of a hæmorrhagic diathesis is congenital absence of fibrinogen Though the defect can be demonstrated without difficulty, the condition may be overlooked because of its rarity, for only eight or nine cases have been recorded, the first in 1920 by Rabe and Salomon In the following case, which showed all the features of this interesting state, a necropsy was performed.

CLINICAL RECORD

The patient, an architect's assistant aged 19 was admitted to the Essex County Hospital on Nov 19, 1947, complaining of pain in his chest

History —From the time of his birth, when his cord bled profusely, he had lost large amounts of blood from minor injuries and had always bruised easily The main bleeding episodes, previously attributed to hæmophilia, were

Age (years)	Injury sustained	Treatment given
3	Minor crush injury to finger	Three weeks in hospital Treatment unknown
7	Cut finger	Snake venom applied without effect $^1/_2$ pint of his mother's blood stopped the bleeding
8		Fortnight in hospital Transfusion
10		Bleeding controlled after the second bottle of blood Had a minor operation on his finger immediately after but had no trouble from this
11		In hospital Bleeding controlled by transfusion
13	Perforating injury to foot	Fresh blood applied locally stopped the hæmorrhage

His only other illness was whooping cough in infancy

There was no family history of bleeding His parents came from different parts of the country and there was no known consanguinity in the last three generations A sister and brother are both alive and well

In October 1947, he developed headaches and pain down the back of his neck, sweated profusely, and felt very weak He had a spontaneous epistaxis for which he was admitted to hospital and given 1500 ml of blood This controlled the hæmorrhage and he was again discharged A week later he began to get pain shooting across the right side of his chest, and he was admitted to the Essex County Hospital for the first time

Examination —He was lean, but otherwise normally developed He had a pyrexia of 100–102°F and persistent tachycardia 110–140 per min respirations were 30–35 per min Physical signs indicated a large collection of fluid in the right pleural cavity and this was confirmed radiologically His joints showed none of the changes to be expected in a hæmophilic

Blood Examination —Hæmoglobin 70%, red cells 3,600,000 per c mm, white cells 25 000 per c.mm (polymorphs 96%, lymphocytes 3%, monocytes 1%), platelets 280,000 per c mm Bleeding time 6 min 30 sec (Duke's method) Clotting time no clot after 2 hours (capillary tube method)

Course of Illness —Aspiration of the chest yielded 28 oz of turbid dark-brown fluid containing many polymorphs and red blood-cells and scanty epithelial cells No organisms were revealed by Gram or Ziehl Neelsen staining Aerobic and anaerobic cultures were sterile

As he had been treated with sulphonamides before admission, a provisional diagnosis of pneumonia, sterile empyema, and hæmorrhagic diathesis of unknown ætiology was made During the next few weeks, however, the pleural effusion re formed repeatedly after aspiration The five aspirations all caused considerable oozing from the puncture wound, and the later ones showed increasing proportions of lymphocytes to polymorphs No organisms were seen in direct films all cultures were sterile, and all cultures for tubercle bacilli were negative Two inoculated guineapigs were free from tuberculosis after six weeks Four specimens of sputum were examined and two were cultured for tubercle bacilli with negative results

On Dec 4 it was decided to remove as much fluid as possible and replace it by air After withdrawal of 7 pints, radiography next day showed a completely collapsed right lung and a residue of fluid at the right base During the next two weeks signs of consolidation developed at the base of the left lung and the patient began to cough up heavily bloodstained sputum A transfusion of 2 pints of blood on March 11, 1948 brought temporary improvement and on April 2 a further transfusion with 80 ml fibrinogen solution and 3 pints of blood was given But his clinical condition deteriorated, and on April 6 he became cyanosed and dyspnœic, and died

SPECIAL INVESTIGATIONS

On March 16, 1948, the erythrocyte sedimentation rate had been estimated and it was noted that the fall in 1 hour was 5 mm, an exceptionally low value considering the patient's state This, coupled with the fact that his X-ray films showed a deficient fibrin formation, suggested that the case might be one of congenital afibrinogenæmia A further series of experiments was therefore undertaken

1 A specimen of the patient's fresh whole blood was incubated at 37°C for three days No clot formed

2 His plasma was heated to 60°C No fibrin was precipitated

3 Quarter saturation of the plasma with ammonium sulphate failed to bring down a precipitate of fibrin

From these three tests it was concluded that the patient was completely lacking in fibrinogen

4 Prothrombin time was estimated by Quick's method The control clotted in 12 sec With the patient's plasma, a faint granular precipitate appeared after a few seconds, but no clot or flakes of fibrin Quick's test was again carried out using as a control 50% normal plasma diluted with saline and the patient's plasma to which was added an equal volume of 1 2% solution of fibrinogen The control clotted in 21 sec and the patient's plasma in 6 min.

From this it was deduced that the patient's blood contained some prothrombin

5 *The Bleeding time* —In the eight cases reviewed by Henderson et al (1945) the bleeding times varied between 5 and 30 min and in the case described by Pinniger and Prunty (1946) it was $3^1/_2$ min In the present case the shortest bleeding time recorded was 1 min. (Ivy's method), using the smallest prick necessary to draw blood, and the longest time was 20 min. Pricks of the finger pulp always stopped

bleeding within 2–3 min , whereas bleeding caused by the aspiration needle in the chest wall went on for several days Bleeding sometimes stopped temporarily and recurred in about 20 min , presumably as the temporary contraction of the capillaries (Macfarlane 1945, 1948) wore off

The bleeding time therefore, even when uncomplicated by clotting, gave results which varied widely according to such factors as the rate and degree of capillary contraction, the support offered by surrounding tissues, the depth of the prick and possibly the speed and completeness with which platelet agglutinates plugged the vessels

6 *Capillary Fragility* —As in most of the previously reported cases, the capillary fragility (as tested by Hess s method) was not increased, and capillary microscopy showed normal response of the capillary to injury

7 *Erythrocyte sedimentation Rate* —An attempt was made to compare the sedimentation of the patient s blood and ' defibrinated " blood (made by adding cells to a serum, which before defibrination sedimented at 50 mm per hour) Measured at fifteen minute intervals over 3 hours the two sedimentation curves showed a similarity, a fact which might be held as doubtful evidence that other globulins were present in the patient's plasma in approximately the proportions that would be expected from his condition Rouleaux formation, though present in wet-blood preparation, was not conspicuous

8 *Agglutination* —Apitz (1937, 1939) postulated a precursor of fibrin which he called " profibrin " and suggested that platelet agglutination depended on the coating of the platelets with this substance It has also been suggested that certain forms of erythrocyte agglutination depend on this factor (Quick 1942) Accordingly, blood grouping and rhesus grouping were carried out under the microscope , but no abnormality was noted in the agglutinated clumps The platelet agglutinates in wet-blood film preparations were also examined but appeared to be normal The fragility of the red cells was normal In this case, therefore, unless the fibrinogen was present in very minute amounts, its product " profibrin ' did not appear to exert any obvious influence on agglutination

9 The platelets were counted twice, and on the first occasion were 280,000 per c mm and the second 420,000 per c mm Of the other eight reported cases, only two showed a temporary thrombocytopenia

10 *Investigation of Relatives* —Two of the cases described previously had relatives showing a hæmorrhagic tendency We therefore carried out fibrinogen estimations and clotting times on all our patient's available living relatives All reports fell within the limits of normal except that a maternal aunt on two occasions had a plasma fibrinogen of 0 12% She had had no ' bleeding incidents " and her blood clotted and retracted normally

POST MORTEM FINDINGS

Necropsy (April 6)

Wasting An ecchymosis in the right forearm surrounding the site of a venepuncture Right chest considerably flatter than left

Cardiovascular System —No clotting was found in any of the vessels or the heart The pericardial cavity contained 3–4 oz clear, serous fluid The heart appeared normal, though the muscle was pale

Respiratory System —The trachea and bronchi were filled with bloodstained mucus On the left side there was 8 oz of clear brown fluid The visceral and parietal pleuræ were studded with nodular thickenings particularly over the upper lobe and along the line of division between the upper and lower lobes Both lobes of the left lung showed confluent tuberculous bronchopneumonia apart from a small area at the apex There was considerable infiltration of fibrous tissue in the lower lobe

On the right side the pleural cavity was completely obliterated by adhesions , the adherent layers which were $^1/_4$ in thick, surrounded a shrunken fibrotic lung The upper lobe was normal

Abdomen —The liver was enlarged (8 lb) , its surface was smooth and it showed a normal pattern. The cut surface was firm and the cut edge bulged out below the capsule The lobular pattern was distinct, but the whole organ was paler than normal The spleen (10 oz) was approximately double the normal size, and the cut surface was red and diffluent The kidneys, ureters, and bladder were normal The stomach was filled with altered blood but no other abnormality was found in the alimentary tract

All other organs were macroscopically normal.

Morbid Histology

The *liver* showed slight fatty degeneration at the periphery of the lobules and moderate albuminous degeneration Scattered throughout there were very scanty giant-celled tubercles There was no microscopical cause for the great increase in weight

In the *spleen* the malpighian bodies were enlarged with plasmacytoid mononuclear cells, polymorphs, and round cells with a rim of pale eosinophil cytoplasm and nuclei resembling those in the outer part of the malpighian body Four giant celled tubercles were found in one of these sections.

The *sternum* showed a normal bone structure The marrow was very cellular and a single giant celled tubercle was seen There were, however, groups of hyaline, palely eosinophil masses resembling necrosed bone surrounded by granular debris

All sections of the *lungs* showed confluent giant-celled and caseous tubercles and acute necrotising tuberculous pneumonia The collagen fibres of the visceral pleura were separated by œdema fluid and there were scanty included tubercles Groups of alveoli in the lungs contained eosinophil hyaline coagula (œdema fluid), but none of them showed gram positive fibrin, and no fibrin strands were seen on the pleura Sections of the lung, stained by the Ziehl Neelsen method, showed acid fast bacilli in large numbers

The sections of skin, kidneys, myocardium, and pancreas were normal

DISCUSSION

The rarity of this condition is the only stumbling block in diagnosis, which, when reached, is irrefutable From the eight cases reviewed by Henderson et al (1945) the main features were shown to be

1 A hæmorrhagic tendency from birth.
2 Easy bruising
3 Sometimes consanguinity between the parents
4 A poor prognosis (4 patients died in childhood)
5 A very slow constant sedimentation rate
6 In all cases an absolute afibrinogenæmia and absence of clotting

The present case conforms well with these criteria

With regard to the fibrinogen and blood transfusions given three days before the patient's death, if it is assumed that there was a circulating fluid of $5^1/_2$ litres at the end of the fibrinogen transfusion (containing 0 96 g of fibrinogen) his plasma fibrinogen should have been in the region of 0 017 g per 100 ml A specimen of blood was taken at this stage and incubated for twenty four hours, at the end of which time no clot had formed In fact, with only this small amount of circulating fibrinogen, a soft gelatinous clot will form in whole blood

Immediately after the fibrinogen transfusion 1000 ml of whole blood was given, the equivalent of 3 g of fibrinogen This in itself should have raised the patient's plasma fibrinogen to 0 055 g per 100 ml —an amount capable of producing quite a solid clot A blood sample taken after this transfusion, however, again failed to clot An explanation might be that because of his multiple tuberculous lesions the fibrinogen was utilised from the circulation as soon as it was put in On the other hand, examination of sections did not reveal fibrin Possibly the amount was too small to detect by this method

Pinniger and Prunty (1946) transfused their patient with 300 ml of a concentrated solution of plasma and took specimens of blood at intervals They were able to show the presence of clotting three days after transfusion, and flakes of fibrin were detected after eight days

The modification of the tuberculous lesions by the lack of fibrinogen is difficult to assess Immunity must depend partly on the localisation of bacteria by fibrin, and indeed this patient had extensive disseminated tuberculosis The fluids aspirated from the chest did not contain clots and it is interesting to surmise how the collagenous pleural adhesions still formed despite the apparent lack of a fibrin scaffold

The significance of the relative lack of abnormality of the enlarged liver is not very clear. It seems that if fibrinogen is indeed manufactured in the liver its absence does not produce any obvious pathological change in the cells, and whether the enlargement is the result or the cause of the afibrinogenæmia is not plain. Certainly the small number of tubercles in it could not be responsible for such a degree of hepatomegaly.

SUMMARY

A case of congenital afibrinogenæmia complicated by tuberculosis is described. The clinical and pathological features are compared with those of previously reported cases.

I would like to thank Dr S. A. Propert for permission to publish this case, and Dr D. J. O'Brien for making the histological examinations.

POLIOMYELITIS AND POLIOENCEPHALITIS WITH OPSOCLONIA FOLLOWING APPENDICECTOMY

M. D. WARREN
M.B. Lond.
LATE RESIDENT MEDICAL OFFICER,
HERTFORD COUNTY HOSPITAL; SQUADRON-LEADER, R.A.F.

THERE is an increasing number of reported cases of poliomyelitis in which a relation appears to exist between previous trauma and the site of maximum paralysis.

As long ago as 1910 Sheppard, in Massachusetts, noticed a relation between tonsillectomy and the onset of poliomyelitis. Reviewing many of the subsequent reports Aycock (1942) concluded that the proportion of cases of bulbar poliomyelitis following tonsillectomy was significant. This observation has been confirmed by Rhodes (1947) and other workers.

McCloskey (1950) and Geffen (1950) have observed an association between prophylactic immunisation and poliomyelitis, the inoculated limb being affected more severely. These observations were noticed particularly after pertussis or combined pertussis-diphtheria inoculations. A similar phenomenon has been reported after injections of T.A.B. vaccine and penicillin (Russell 1949). Possibly some similar cases of poliomyelitis were included among the shoulder-girdle syndrome described as localised neuritis by Spillane (1943) and as neuralgic amyotrophy by Parsonage and Turner (1948).

Many precipitating causes have been suggested, including tooth-extraction. This is a common operation and therefore information about the relationship is more readily accessible. Aycock (1942) summarised the then available evidence as follows: "It would appear that this reported circumstance can be relegated to the category of miscellaneous precedent events of no ætiologic significance." This view still holds.

The association with appendicectomy has only rarely been reported.

CASE RECORD

A boy aged 7 years was referred to the surgical outpatients department of Hertford County Hospital on Aug. 20, 1946, and was seen by Mr W. Donald Bedford. He had had intermittent attacks of epigastric pain during the last year. His doctor had seen him during the attacks and considered that these were due to appendicular colic. The child had had pneumonia three years previously but otherwise, except for the attacks already mentioned, he had been quite well. He had had no headaches, and his bowels had been generally regular. On examination the ileocæcal glands were palpable, and in view of the history the child was admitted for appendicectomy.

Operation.—Mr Bedford removed the appendix on Sept. 5, 1946. The child was premedicated with Nembutal gr. 2 and atropine gr. $^1/_{100}$. He was anæsthetised by Dr H. S. H. Gilmer with thiopentone, gas, oxygen, and 'Trilene.' Through a Battle's incision a long kinked retrocæcal appendix was removed. The wound was stitched up without drainage tubes. For three days after the operation the child had a mild pyrexia in the evening (99.0°–99.8°F). However, the wound healed satisfactorily, the temperature settled, and he was discharged to convalescence at home on the seventh post-operative day.

Readmission.—On Sept. 17, twelve days after his operation, he was readmitted. On Sept. 15 his parents had noticed that he was hot and delirious ('saw envelopes on the wall'). Later on Sept. 15, he had become rational; that night he had vomited. Next morning he had again been delirious, and his temperature had been 104°F. He had spent a restless night, and on Sept. 17 he had once more become rational. On admission he complained of a severe basal headache and of pain in the lower abdomen. He had no limb pains or backache. Temperature 101°F; pulse-rate 128. His abdomen was grossly distended and tympanitic, and his bladder was distended up to the umbilicus. He was also tender over the right kidney and could not sit up. There was a mild degree of neck rigidity. Further questioning of the parents revealed that the child had passed very little urine since Sept. 16 and had been constipated since the 15th. Mr Bedford suggested the diagnosis of acute poliomyelitis.

Course of Illness.—On Sept. 18 the paralysis had spread to the neck muscles. No urine had been passed since a small amount after admission, and 19 oz. was withdrawn by catheter. Next day the temperature had settled to normal, but there was complete flaccid paralysis of the legs except for some plantar flexion. No tendon jerks could be elicited. Lumbar puncture on Sept. 18 produced clear cerebrospinal fluid containing total protein 90 mg. per 100 ml. and 49 white cells per c.mm. (report by Dr V. Magee). The urine, sp. gr. 1.012, contained nothing abnormal except acetone. Blood-culture was sterile, and a blood-count showed Hb 15 g. per 100 ml., red cells 5,580,000 per c.mm., colour index 0.99, white cells 18,600 per c.mm. (filamented polymorphs 74%, non-filamented polymorphs 4%, lymphocytes 20%, and monocytes 2%).

On Sept. 19 cyanosis and respiratory embarrassment were noted. The accessory muscles of respiration were being used, and by the evening it was necessary to put the child into an "iron lung." At the same time weakness of the shoulder-girdle muscles and wrist-drop developed. During the next three days catheterisation continued to be necessary and the bowels were not opened.

His condition remained much the same, except for restoration of function in the bladder and bowels, until Oct. 2. During this time he was apyrexial, except for an evening temperature of 99°F on Sept. 26, 27, and 28. His pulse-rate was 104–132. On Oct. 2 he was removed from the "iron lung" for an hour, and this period was gradually increased until on Oct. 15 he was removed completely from it. Since Sept. 20 splinting to prevent muscle stretching, and passive movements and massage had been instituted as indicated by the palsies.

On Oct. 11 he had a pyrexia of 99°F and he continued to have a temperature fluctuating between 98.6° and 100°F until his death on Oct. 23. His general condition seemed to remain static until on Oct. 18 he developed twitchings of the right side of his face and his right arm and was incontinent of urine and fæces. This attack recurred on and off during the day. Towards evening the right arm was no longer involved but three new features had developed: he became cyanosed during the attack; he lost consciousness for periods of about an hour; and he had a peculiar oscillation of his eyes, which seemed to roll in a circular movement. The attacks continued on Oct. 19, and the child was delirious, disoriented, and hallucinated. Polioencephalitis was diagnosed.

On Oct. 20 he became unconscious and was given intramuscular penicillin 20,000 units three-hourly as a prophylactic against pneumonia. He died on Oct. 23 without having regained consciousness. Permission for a necropsy was not given.

DISCUSSION

The incubation period of poliomyelitis is considered to be 7–17 days and is usually about 14. This lad developed his first symptoms 10 days after his operation and was therefore in or near the incubation period at the time of the operation The first signs—i e, paralytic ileus and a paralysed bladder—occurred in the area of trauma Gaustad (1948) recording a case of poliomyelitis seven weeks after appendicectomy, noted that the muscles near the operation site were paralysed, particularly the right psoas Mills (1947), however, reported that 3 of 33 cases of acute poliomyelitis in which no operation was performed developed paralytic ileus The symptoms of bowel paralysis appeared three days after the first onset of paralyses in the voluntary muscles and in all 3 cases there were absolute constipation and retention of urine Mills advised the use of neostigmine 0 5 ml daily, but in the present case normal function returned after five days, and except for catheterisation no other treatment was thought necessary for the paralytic ileus Critchley (1948) pointed out that in the 1947 epidemic "retention of urine was frequently encountered in the poliomyelitis patients both before the onset of paralysis and after"

The peculiar ocular movements in association with polioencephalitis were first described by Orzechowski (1927), who called them opsoclonia Marmion and Sandilands (1947) described a case in a boy, aged about 3 years, who developed in both cases rapid jerking nystagmoid movements occurring in groups of up to six The movements occurred in horizontal, vertical, and oblique directions and came on with attempts to fix the gaze Their case also showed rapid head-nodding tremors The boy did not develop paralyses and reco completely McAlpine et al (1947) reported a similar Other eye signs reported are diplopia, nyst ptosis, and complete paresis of the occulomotor (*British Medical Journal* 1947)

Finally, the recurrence of symptoms, and the of polioencephalitis, four weeks after the initial s toms of poliomyelitis, appears to be unusual, an encephalitis in this case was also exceptionally widesp

I wish to thank Mr W D Bedford, consulting s to Hertford County Hospital, for permission to publi case record, and Air Marshal P C Livingston, Di General of the medical branch of the Royal Air For permission to publish

New Inventions

A TIDAL SPIROMETER

ONE of the difficulties in using muscle relaxants in anæsthesia is to know when and how much to give An objective method of determining the patient's requirements is desirable Since respiratory depression is the most easily demonstrable effect of these drugs, an instrument for measuring the tidal volume was considered Harbord[1] described an apparatus consisting of a tap by which a single expiration can be deflected into a 600 c cm bag The tidal volume is obtained by estimating the distension of the bag—e g a quarter full or half-full The apparatus described here (fig 1) is more accurate

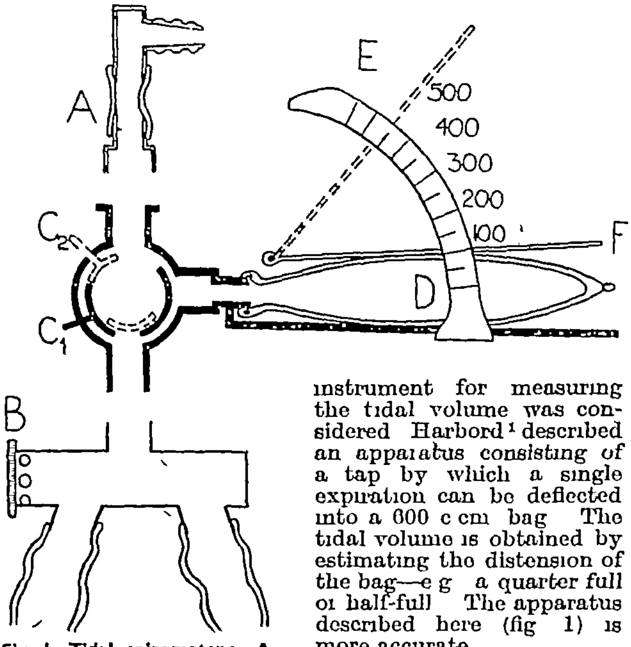

Fig 1—Tidal spirometer: A, endotracheal connection B, expiratory valve mount C rotating drum; D bag; E, scale; F, 'Perspex' plate

A by pass is fitted between the endotracheal connection A and the expiratory valve mount B, it contains a rotating drum moved by a lever C When this is in position 1 the patient s respirations pass to and from the anæsthetic machine, when the lever is in position 2 respiration takes place in and out of a 600 c cm bag D A hinged 'Perspex' plate F re on the bag moves up and down with the respiration, a calibrated scale E is provided along which the move of the plate can be read

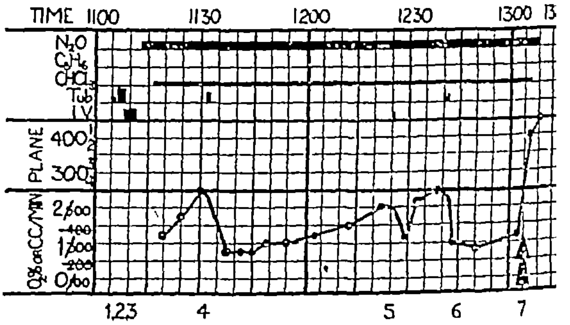

Fig 2—Upper portion of Nosworthy chart. Numbers on left in se plane ' and ' O_2% have been altered to show tidal volu c cm : this is given by lowest curve Injections: 1 tubarine 5 2 tubarine 15 mg 3, thiopentone 0 75 g 4, tubarine 10 m thiopentone 0 2 g 6 tubarine 7 mg 7, prostigmin 2 5 atropine gr $^{1}/_{75}$

When in use the spirometer lies beside the pati head, if covered by the drapes these can be raise the short time required Anæsthesia is maintained in usual way, the additional dead space is 50 c cm measure the tidal volume the lever is moved into pos 2 If this is done at the end of inspiration, an expir will be caught in the bag, but it is better to press reservoir bag on the machine while the lever is mo to be sure that the spirometer bag will not collapse du inspiration, for this would give a false measurem It is generally sufficient to observe two or three res tions, the lever is then moved back to position 1 the anæsthetic is continued The circuit must be airt and a cuffed tube is best, but the instrument can be with a face piece if this fits closely In this way est tions can be made at the bedside The instrument also be placed on the anæsthetic machine, between reservoir bag mount and the corrugated tubing, when semi-closed technique is in use

The tidal volume can be measured at regular inte —e g, between blood-pressure estimations The res tory rate should be counted at the same time in ca is desired to know the minute volume The tidal vol can be charted on the Nosworthy card in the sp marked "plane" and "O_2%" An example (fig given of a record made during a partial gastrectomy, and the effects on the tidal volume of injections of 'Tubarine,' thiopentone, and 'Prostigmin' are shown

---

[1] Harbord, R P *Brit J Anæsth* 1948 **21**, 94

When this instrument has been used, an increase in the tidal volume has always preceded the return of muscle tone, and can be taken as an indication for a further injection of muscle relaxant The intensity and duration of the effect of the previous dose is of assistance in estimating how much more to give

Thanks are due to Dr John Gillies for his encouragement and assistance, the spirometer was made by Mr J P Morison of the department of anæsthetics, Royal Infirmary, Edinburgh

Reviews of Books

Virus and Rickettsial Diseases

S P BEDSON, F.R.C P, F R S, professor of bacteriology, London Hospital, A W DOWNIE, M D, professor of bacteriology, University of Liverpool, F O MACCALLUM, M.D, director of the virus laboratory, Central Public Health Laboratory, C H STUART HARRIS, F R C P, professor of medicine, University of Sheffield London Edward Arnold 1950 Pp 383 24s

The Pathogenesis and Pathology of Viral Diseases

Symposium held at the New York Academy of Medicine, Dec 14–15, 1948 Editor JOHN G KIDD New York Columbia University Press London Oxford University Press 1950 Pp 235 32s 6d

An Introduction to the Study of Viruses

K. M SMITH, F.R S, director of the plant virus research unit, Molteno Institute, Cambridge London Pitman & Sons 1950 Pp 106 10s 6d

THESE three books on viruses are all handy volumes, written by experts, and well produced But there the similarity ends

Bedson and his colleagues deal with only the virus diseases of man, and try "to present a coherent readable account rather than an exhaustive treatise" In this country their book will be by far the most useful of the three The main facts are all there for senior students, bacteriological and public-health workers, and clinicians who want to keep up to date in this subject, and though the book is not primarily intended for those working on viruses it will be helpful to them nevertheless The scene is apt to change between the writing of a book and its publication, and probably the authors would today be less hopeful about the use of ultraviolet irradiation as a means of destroying hepatitis virus in plasma, and would say something about poliomyelitis in relation to inoculation, and more about the Coxsackie viruses. Epidemic keratoconjunctivitis, however, seems to be the only important human virus infection omitted The four introductory chapters, three of them by Professor Bedson, are particularly good

The book on virus pathology edited by John Kidd will appeal to a smaller circle, mainly of laboratory workers but it is full of good things R E Shope discusses the spread of viruses, illustrating his story particularly by references to some of the epidemiological puzzles he has himself helped to solve, T F Anderson gives a stimulating account of adsorption co factors in infection of bacteria by 'phages, and Wyckoff's descriptions and pictures show beautifully developments in the field of virus electron micrography Most of the other chapters are illustrated by well-produced photomicrographs, showing such things as the pathological changes caused by yellow fever, and various neurotropic viruses A chapter on cardiac lesions contains some little-known data, and Kidd himself writes well on proliferative lesions caused by viruses

In the third book Dr Kenneth Smith has had the idea —theoretically sound—of treating side by side the viruses attacking plants, animals, and bacteria He deals adequately with the plant viruses, but his knowledge of animal viruses is sporadic The virus field is now so extensive that no one author can hope to cover the whole of it

Primary Carcinoma of the Vagina

R G LIVINGSTONE, M D, formerly member resident staff, Gynæcological Division, Memorial Hospital for the Treatment of Cancer and Allied Diseases, New York City Springfield, Ill Charles C Thomas Oxford Blackwell Scientific Publications 1950 Pp 73 15s

IN 20 years, only 110 cases of this form of cancer were collected at the Memorial Hospital, New York—representing a low incidence, as reported elsewhere Clinical findings are well described in this little book, and the relative incidence of genesis from different parts of the vagina is given The notes on treatment by radiotherapy are of little use because of the failure to indicate the dose of irradiation received by the tumour Surgical treatment is now advised, but no long-term results are yet available The 5-year survival was 8 out of 85 cases, a figure resembling that usually quoted for this type of cancer, which for some reason is much harder to treat than cancer in the adjacent cervix

Health and Disease in the Tropics

CHARLES WILCOCKS, M D, F R C P, director, Bureau of Hygiene and Tropical Diseases London Oxford University Press 1950 Pp 200 15s

DOCTORS, whether they are practising in the tropics or not, will find this book useful, but it is written primarily for the lay administrator, the non-medical missionary, and in fact for anyone who lives in or proposes to live in a tropical country The administrator, whether in government service or commerce in the tropics, has to have a much greater knowledge of medical subjects than his counterpart in temperate zones, partly because he may at any time find himself out of reach of medical aid, and partly because health—his own, his family's, and that of people for whom he is responsible—needs much more care than in a country with a well-organised public health service Dr Wilcocks opens and ends his book with homilies on collaboration all departments must work together, and to do that each must understand the point of view and difficulties of the others After a very simple exposition on the causes of disease, he discusses groups of diseases Treatment is given in outline only, nowhere is the reader encouraged to treat himself, and in some instances special warnings are given of the danger of attempting this There are useful chapters on housing, water supplies, drainage, and public health A section on organisation and personal protection concludes this sensible and informative book.

Therapeutic Radiology

GEORGE WINSLOW HOLMES, M D, former radiologist in chief, Massachusetts General Hospital, MILFORD D SCHULZ, radiologist at the hospital London Henry Kimpton 1950 Pp 347 52s 6d

THE opinions expressed in this book, the authors tell us, are very largely those of the tumour clinic of the Massachusetts General Hospital They have limited the discussion of radium therapy to ancillary procedures where there is a choice between radium and X rays the method using X rays has been described Bearing this limitation in mind, readers will find much to interest them in this description of radiotherapy as practised in a major American centre An early chapter, illustrated by coloured photographs, of the effects of röntgen rays on the living cell, shows the striking effects of excessive dosage—which may seem premature to the reader who has not yet been told the biological dosage recommended at the centre The choice of dose and technique is considered fully later, but the use of dose in air is allowed to confuse the calculation of depth-dose in relation to skin dose The sections on the treatment of tumours in various sites are sound The emphasis is rightly on surgery for cancer of the breast, but the condemnation of preoperative X-ray therapy seems rather sweeping For cancer of the oral cavity X-ray therapy is advocated in sites where radium is probably the better alternative, and in the chapter on diseases of the central nervous system the treatment of medulloblastoma is said to be merely palliative, though this tumour can be cured in the sense that patients have survived ten years without recurrence. The importance of radium therapy for cancer of the female genitalia is recognised, though with the method recommended serious high-dosage effects are likely to follow In general, some first-class accounts of clinical cases and the processes of malignant disease are not supported by good descriptions of radiotherapeutic techniques

Cell Physiology and Pharmacology

J F DANIELLI, professor of zoology, King's College, London London Elsevier, Cleaverhulme Press 1950 Pp 150 24*s*

THIS valuable book gives much information tersely yet readably The author, with considerable success, attempts to integrate biophysics, quantitative biochemistry, and quantitative pharmacology at the cellular level The work is based on a series of lectures delivered at University College, London, and directs attention to factors which are important for students of drug action It is not intended as an exhaustive study of the place of cell physiology in pharmacology

Documenta Ophthalmologica

Editors F P FISCHER, Utrecht, A J SCHAEFFER, Los Angeles, ARNOLD SORSBY, London Vol IV The Hague Uitgeverij Dr W Junk 1950 Pp 302 Dutch guilders 36 (or £3 7*s* 11*d*)

THE present volume is dedicated to Prof Karl Wessely on his 75th birthday It also carries news of the death of F P Fischer, one of the editors, at the early age of 52 It is to be hoped that this loss will not affect the excellence of this series of academic work

Outstanding in this volume are a critical analysis of the quanta theory of vision by M A Bouman, and a detailed record of twin research in ophthalmology by P J Waardenburg An extensive review of fundamental principles involved in the local application of ophthalmic drugs is given by A J Schaeffer, whose contribution is apparently a first instalment of a comprehensive survey of principles of ocular pharmacology Shorter studies on visual purple by Katharine Tansley, on protein deficiency by G B Bietti, on lighting and vision by R G Hopkinson, on tonometry by J S Friedenwald and R Moses, and on protective glasses in welding by G A W Rutgers are all critical reviews

Psychiatric Sections in General Hospitals

PAUL HAUN, M D, assistant professor of psychiatry, Georgetown University Medical School New York Architectural Record 1950 Pp 80 $4

Dr Haun points out that architects in the United States have often treated the psychiatric section of a general hospital as an afterthought He describes the various stages through which the architects and the psychiatrists should consult their way towards a satisfactory, if not ideal, unit

Approaching the matter from a functional rather than a structural standpoint, he considers all the phases of admission, examination, special investigation, nursing, and treatment which a patient will pass through, and then indicates how these purposes can be served The outcome of his way of looking at the architectural problem is a series of clear guiding principles, and considerable flexibility in their application This flexibility is effectively demonstrated in his systematic critical appraisal of eight designs for psychiatric wards in general hospitals, submitted by architects to the Veterans Administration The plan of each of these is shown, and first the desirable and then the undesirable features of the central area (or administrative offices) the "disturbed nursing unit, and the "quiet nursing unit" are listed below it, with reasons It is noteworthy that in these modern designs, reflecting the requirements of the most advanced American psychiatrists, a hydrotherapy unit and a solarium are never lacking a roof garden is also customary though the patients enjoy the use of occupational and similar facilities provided for the orthopædic and other patients on the lower floors The book contains also an interesting set of plans for a complete six floor general hospital, drawn up by two well known New York hospital architects

Though it will be long before we can hope to use these precepts and examples here in any but a few favoured instances, it is valuable to have the book, since it contains much that is suggestive for smaller psychiatric units of the kind that our hospitals will doubtless have to establish before long

A Manual of Cardiology (2nd ed Philadelphia a London W B Saunders 1950 Pp 355 25*s*)—T pocket size book gives clearly and soundly the essentials cardiology Prof T J Dry provides some of the informat in tables or lists, but elsewhere his style is very readab Common conditions get pride of place, but there are sh accounts of such rare conditions as amyloidosis and scle derma One or two small errors have crept in, but in t main the little manual is outstandingly good of its kind.

Whitaker 1951 (83rd annual vol London Whitake Pp 1156 12*s* 6*d*)—This, the largest Whitaker yet printe has recovered its pre war promptness the new volum appeared before the old year died It casts its net as wid as ever, ranging from stamps to stars, from weights to weathe and from films to high finance The Festival of Britain h an article to itself, and is supported by sections on places historic interest in our chief cities and London's cathedr and churches, too, have found their way back Medical a academic readers will be gratified by the return of a list Oxford and Cambridge professors since 1939 we have be without this convenient inventory Perhaps we may ho that next year the learned clerks of London University w be added

Lipidoses Diseases of the Cellular Lipid Metaboli (2nd ed New York and London Oxford University Pr 1950 Pp 595 96*s*)—The difficulty of making pure p parations of the fats and lipoids, and the chemical similar of the various fatty acids found in them, has always made study of these substances a formidable task Neverthel immense progress has been made, and the chemistry of fats and sterols has largely been elucidated, though ther still much to be learnt about their intermediate metaboli Progress has not been so rapid in the study of the lip dystrophies, though a great deal of work has been done them in the last ten years The second edition of Pr Siegfried J Thannhauser s book reviews this progress in light of older work The opening chapter deals with physiology and chemistry of the fats and allied substanc discusses their absorption from the gut, and summarises steps by which the fats, proteins, and carbohydrates may converted one into the other within the body The grea part of the book is devoted to the problems in lipoid me bolism presented by the xanthomatoses, Gaucher s disea and the Niemann Pick syndrome Von Gierke s glycog storage disease is also included by virtue of the associat hyperlipæmia and occasional secondary xanthomas fou in the skin Much of the detail is supplied by the autho own case records and chemical investigations The bo a mine of information, is well illustrated by photograp coloured plates and photomicrographs, and the statemen made are supported by numerous references

D D T and Newer Persistent Insecticides (2nd London Chapman & Hall 1950 Pp '632 50*s*)—The fi edition of this handbook was published in 1946 and contain numerous references to work completed in 1945 In the prese edition, however, there are very few references in the text lat than 1946—though the authors, Mr T F West D SC, and M G A Campbell, have appended a bare list of later reference Nevertheless, the book has doubled in size mainly owing thorough revision and numerous new passages The section on the manufacture and chemistry of D D T contain mor useful data on its solubility in various liquids, its chemic and physical stability its chemical estimation, and th composition of the technical grades A valuable list is giv of the various analogues of D D T, with notes on their insec cidal activity The chapter on formulation includes metho and formulæ which did not appear in the first edition, a these data are all set out in a practical way The autho have collected much information on the toxicity of D D to mammals but this would be easier to follow if it had be arranged under subjects Two defects of D D T first noticed 1947 are omitted One is the irritant action on mosquito of D D T treated surfaces, noted by Kennedy, and consider by Muirhead Thomson to interfere with control of *Anophe gambiæ* the other is the appearance, in many countries, house flies highly resistant to D D T There is a useful chapter γ B H C but only rather inadequate information on other n insecticides This subject however, is moving continuous and it is impossible for a textbook to be entirely up to da Criticisms of this new edition fade into the background behi its substantial advantages

THE LANCET
LONDON SATURDAY, JAN 27, 1951

This Influenza

THIS winter's epidemic of influenza bids fair to be the most extensive Britain has had since 1937—perhaps since 1929 The weekly death-roll in the 126 great towns in England and Wales has risen steeply from 54 in the week before Christmas to 102, 458, and now 890 in the week ended Jan 13, the figures will presumably go still higher, and the steepness of the recent rise is disturbing So far, however, the fatal cases have been mainly in the over-55 age group and very largely confined to people already suffering from cardiac or other chronic illnesses In Merseyside the death rate is approaching its 1918–19 levels, but there is no suggestion in this epidemic of a high mortality among young adults such as was seen in 1918–19, despite the contrary reports in some newspapers

Thanks to the international studies of the last few years we can understand a good deal about the background of this epidemic Influenza virus A is always apt to cause more widespread trouble than virus B Since 1947 the older A strains have been replaced all over the world by a serological variant called A-prime, which was first detected in Australia in 1946 and in 1947 caused outbreaks in America and to a less extent in Britain and Sweden In 1948–49, information and strains of virus sent to the World Health Organisation World Influenza Centre in London made it possible to trace the spread of a virus right across western Europe This, too, was an A-prime strain, slightly different from that of 1947 Starting apparently in Sardinia in the autumn of 1948, the virus soon reached continental Italy, whence it spread to Austria, Switzerland, France, northern Spain, western Germany, and the Low Countries About New Year, 1949, it reached Britain, and so on to Denmark and Iceland Sweden and Ireland were just touched but hardly affected, and Britain was less affected than most of the Continent, perhaps because of her experience of a similar A prime virus in 1947 In June, 1950, local outbreaks of influenza due to an A prime virus were reported in central Sweden On previous occasions such local summer "flurries" have been followed by an autumn outbreak in the same area, so a special watch was kept and batches of experimental vaccine were prepared against the Swedish strain Sure enough, in November influenza appeared in Scandinavia—first in rural Denmark, then in northern Sweden, and soon in Oslo and all over Scandinavia The fact that the first appearance of the present epidemic in Britain was in Newcastle just before Christmas makes it likely that this had a Scandinavian origin Also in mid December, influenza appeared in Belfast and northern Spain It is still a matter for speculation whether the Merseyside outbreak came from Belfast There seem at any rate to have been at least three foci of origin—Scandinavia, Belfast, and northern Spain The infection is now spreading to Eire, up into Scotland, south to London and (perhaps from Scandinavia) into Germany, Belgium, Holland, and France, also from Spain to southern France Iceland and Greenland are affected, probably again from Scandinavia Since Britain and Scandinavia suffered less than the rest of the Continent in 1949 they might be expected to be relatively harder hit this time It will be interesting to see whether the United States become involved, they had a good deal of influenza last year when we had none, and their herd-immunity may still be valid Practically all the major European influenza this year is of the A type, the viruses isolated up to now being A prime strains No clinical infections of the classical severe type have been reported as yet

With proper perspicacity the newly formed general practitioners' section of the Royal Society of Medicine had planned a discussion on influenza for January 17 It was only too clear there that the vast body of knowledge about the influenza viruses built up in the last eighteen years has done little to solve the immediate problems of general practice Dr E P SCOTT, who opened the discussion, even brazenly suggested that influenza was "a disease of doubtful ætiology" (but perhaps he was deliberately "trailing his coat") Discussion centred largely on the differential diagnosis of influenza by clinical criteria from other febrile illnesses, for it was generally agreed that during an epidemic almost anything is liable to be diagnosed as flu It still does not seem to occur to clinicians to make use of the specific serological tests for influenza It is true that these tests are not applicable to diagnosis in the first few days of fever, but after ten days, when the doctor may be getting worried, they might well be helpful Considerable argument followed Dr C H ANDREWES's plea for the abandonment of the misleading term "gastric flu", Sir HORACE EVANS and others agreed that gastro-intestinal symptoms may occur in influenza but that epidemics predominantly gastro intestinal probably have nothing to do with true influenza Speakers differed on the advisability of using antibiotics or a "sulphonamide umbrella" in the more serious cases most were against their indiscriminate use It appears that, as in 1949, penicillin may be disappointing in fulminating cases, especially where staphylococci cause a complicating pneumonia

Current opinion on virus-vaccines seems to be roughly this Where a formolised vaccine against the prevailing type of virus infection is available it will give some, but not 100%, protection With better facilities for following the country-to country course of an epidemic, in future years we should know fairly definitely, as we have this year, what type to expect The problem is then largely economic A monovalent vaccine is likely to be better than a polyvalent one Ideally, manufacturers should keep stocks of vaccines against all the main types so that they can issue the appropriate one as soon as an epidemic threatens

B_{12} as the factor necessary for cure Yet we are not sure whether the most appropriate name for this ailment is not still that which Pye Smith gave it in 1883, the " idiopathic anæmia of Addison "[8]

If the numerous references given by Robb-Smith are arranged in decennial groups, it will be seen that three of the decades—1840–49, 1870–79, and 1920–29—contain as many papers of fundamental importance as all the others put together They correspond respectively with the high tide of the French clinical school and its repercussions in other lands, with the technical improvements of hæmocytometer and hæmoglobinometer, and with the new light brought by Murphy, Minot, and Whipple to a subject obscured by excessive attention to static morphology It is no new idea that knowledge advances not inch by inch but in sudden and exciting bounds, but nobody can say where the advance will come next It is a matter of opinion whether the next phase in hæmatology will be one of expansion or of mere consolidation We shall not emulate the Bartlett brothers in prophecy

Annotations

RUSSIAN PSYCHIATRY

The *Journal of the American Medical Association* recently deplored the fact that in the present world situation the publisher of a book on Soviet psychiatry should need to apologise to public opinion for producing it No such apology, one would like to think, is called for with the appearance here of copies of Wortis's collection of facts and documents on the state of Russian psychological medicine[9] English science, and particularly English psychiatry, are undoubtedly concerned to understand both their Soviet counterparts and Russia as a culture pattern, and the too brief period of friendly contact during the war suggested that neither, given the opportunity of contact, would prove incomprehensible The increasingly paranoid character of international relationships—and of international stereotypes—has also made a psychiatric and anthropological picture of the Soviet culture, its standards, and its motivations, highly urgent for all of us, and a study of Russian psychiatry which gave us a full picture of mental health in the Soviet Union, of the cultural attitude of medical science there, of the political background, and of the philosophical and sociological forces involved, would not fall far short of a complete psychosocial study of Marxism Leninism in action

Wortis's book is a heroic attempt to give a just account of the mind and practice of Soviet society as seen through its psychiatry As a collection of documents, bound together by a commentary which might be headed " how life appears to the intelligent Marxist," it is both informative and fairly comprehensive Yet in a society where conscious politicism and (Western *sociologists* would say) the unconscious forces which underlie it have been pressed so far and so fast, it is virtually impossible to assess psychiatric practice and ideas without wide discursions into general sociology, and without seeing the culture pattern in action The author of this book, though he learnt Russian, was prevented by the Berlin crisis from visiting the U S S R, and his work might therefore have been called " Soviet Psychiatry as Reflected in the Literature " Read as it stands, the picture is naive read, however, against the background of other studies, such as Crankshaw's *Russia and the Russians*, or Prof E H Carr's history of the Russian revolution, the documents at least are highly informative, especially those which deal with the radical change in the Soviet attitude towards marriage, discipline, sexual standards, education, and the validity of psycho analytical concepts, which coincided roughly with the Stalin Constitution Admirable as Wortis's attempt at a strictly factual picture may be, it is difficult to assess Soviet *mental health without reference to its public* manifestations—on the one hand the remarkable endurance of the war years and the hardships and achievements which preceded them, and on the other hand the outbreaks of paranoia against Trotskyists We should be obliged to consider factors like these in any assessment of our own society, and in dealing with one less familiar it is all the more necessary Wortis's own assessment is perhaps indicated by his comment that " a deep conviction in the power of reason is strikingly illustrated by the complete absence of a literature on the psychology of propaganda in the U S S R "

From the documents, a very clear picture of Russian psychiatric thought does nevertheless emerge In general it is Pavlovian, functional, based on a far more definite dogma of the mind body relationship than our own, intensely conscious of its social context Its therapeutics make full use of the integrative effects of work and social purpose, which are the strongest psychological cards of any order based on a strong corporate ideology in one case report we find a child therapist using controlled projection against an outside enemy (the Germans) as a deliberate outlet for fear and hate arising from the experiences of the occupation The Russian attitude to Freudian and post Freudian theory is very close to that of the more sceptical English eclectic, or even the older general practitioner, though it substitutes ideology for " common sense " as a ground for its scepticism The sexual orientation of Communism is an important marker for the social psychologist After a brief period of rather wild experiment this has become increasingly similar to that of the English middle class Homosexuality was made punishable in 1947, divorce by consent was ended earlier Capital punishment, after being abolished, was reinstated " by overwhelming public demand " for offences involving treason and sabotage[10] The interposition of attempts at reconciliation before the courts between would be divorcees may foreshadow a line of development in our own divorce law Giliarovsky's statement on normal sexual development[11] sounds remarkably familiar

> " Because psychological sex interests may often develop before physical sex maturity, precocious sexuality should be discouraged We cannot consider it normal for an adolescent of 14 to 16 to have practical experience in sex matters from the point of view of mental hygiene it may be regarded as generally undesirable for sex practices to begin before the age of 17 or 18 It is desirable that sex relations, as far as possible, take place without contraceptives and with a view to conception It is extremely important that the sex act produce complete psychological as well as physical satisfaction There is no reason to believe that sex abstinence in itself can cause any serious mental disturbance, let *alone a psychosis* "

The book contains little on the bitterly debated subject of the Soviet penal system

On the credit side, the successes of Russian psychiatry are essentially the successes of Communism The bitter political struggles and economic hardships of the early days, the struggle over collectivisation, the purges of the '30s, and the appalling character of the Nazi invasion have not succeeded in destroying the morale or the dynamic appeal of Communism, and Russian psychiatry, ca in exploiting the integrative powers of the ideology, effect a synthesis of medicine and social outlook which is far harder to achieve in any culture that has a less intense sense of social purpose. These successes have been gained at the price of intellectual rigidity, and of the forfeiture of the critical approach to psychosocial medicine and to the dynamics of power on which we in Western cultures today pin much of our hope of social progress. There is no doubt, however, that such an ideology provides, to the young in particular, a source of enthusiasm comparable to that derived from the major proselytising religions, and very similar in structure. Perhaps the rudest shocks to those unacquainted with Soviet scientific polemics (or with the theological debates of the English Puritans) come from the appendices to Wortis's book, containing criticism of psychological textbooks on the grounds of objectivity vis à vis the class struggle.

Psychiatry in England can learn much, both from the refusal of Marxist psychiatry to dissociate social, political, and mental health, and from the history, successes, and blemishes of Communism in practice. It is on every count essential that we should understand modern Russia, and that we should do so as scientific observers, despite the difficulties imposed by the suspicions and the propaganda of both sides in the present international tension. For this reason if no other, Wortis's book is valuable to all interested either in psychiatry or in political psychodynamics.

FAMILY STUDIES IN CHILD HEALTH

THE increasing emphasis on child health is one manifestation of the importance now attached to preventive medicine. The conception of long-term field studies of the child in his natural environment is fairly new. The most notable are those being conducted in Newcastle upon Tyne by Sir James Spence, and in Luton by Dr. R. M. Dykes, with their respective teams. These projects are already yielding a rich harvest of facts which will prove of great value in framing enlightened health policies. Dykes[1] reviewed the health of the 1498 infants born in Luton in 1945 who could be observed throughout the first year (these comprised 79% of the total births) and showed that constitutional factors greatly influence child health, and also that the infant-mortality rate is a more sensitive index of social standards than the infant morbidity rate.

The carefully planned domiciliary study of the child which is being carried out in Newcastle is probably the most comprehensive of its kind ever to be undertaken. The objects and methods of this investigation were described in Boston last year by Spence,[2] who discussed some of the data yielded by the first year's work. After tracing the evolution of "preventive pædiatrics" and mentioning the importance of medical statistics, hospital pædiatrics, and laboratory research, he emphasised that much further progress can be made by field workers who go outside the hospitals into the community, to study the incidence and spread of disease, the effects of social conditions on disease, and the control of disease and promotion of health by social environment. He deprecated the idea that field work is something entirely divorced from clinical and laboratory medicine, and suggested that a considerable proportion of those who work in social medicine should be clinicians and laboratory workers who follow their problems into the field when necessary. He pointed out that field inquiries are laborious, diffuse, and difficult to control with scientific standards—these are indeed the main reasons for their former neglect. He also asserted that, although research on some aspects of social medicine concerned with family life can best be conducted by a general practitioner who lives in the community as the family doctor and keeps records of each individual from year to year and from one generation to another, the isolated inquiries of a general practitioner are applicable only to limited subjects; moreover, few general practitioners have the time, training or inclination for such work. For particular purposes such as those which the Newcastle workers are pursuing, efficient organisation and team work are necessary.

The Newcastle city health authorities have shown themselves anxious to coöperate with the university department of child health, the children's hospitals, and the laboratory services in field research to improve child health. An initial coöperative investigation into the causes of infant mortality in Newcastle in the year 1939 was directed by Miller.[3] The most notable finding was wide disparity between notified causes of death and actual causes as revealed at necropsy—a finding that indicates the inaccuracy of vital statistics relating to causes of death in infancy. A domiciliary study of morbidity in the first eight years of life was inaugurated in 1947; the work was greatly helped by the team spirit and technique evolved during the earlier mortality investigation. The main object was to observe, against the background of the home, the acute infective illnesses of young children—their incidence, clinical types, and results. Other objects were to bring those working in wards and laboratories into daily contact with field workers, thus broadening their concepts of health and disease; to provide relevant local facts with which to freshen clinical teaching; to guide health programmes; and to create a method for giving a contemporary picture of disease, verified by statistics and direct clinical observation, which would reveal new problems for research. It was decided to study from the day of birth a sample of 1000 infants—one sixth of Newcastle's annual births. Altogether 1142 infants, born in May and June, 1947, were selected, representing a cross-section of all social groups. The team of investigators consisted of one pædiatrician who devoted most of his time to the research; two more senior pædiatricians for consultation; two clerks; and five specially trained health visitors, who were entrusted with much of the intimate observation and research. Each week's collected material was discussed at a Saturday conference attended by the medical officer of health and others concerned. As Spence aptly remarked, this study of 1000 infants inevitably became a study of 1000 families.

Although this investigation has not yet reached the half-way point it has already yielded much valuable information. The records show in detail how 1000 families drawn from all social classes live, how they react to the problems of life, how they avail themselves of the health services, how the children are nurtured in body and mind, what their activities are, and the relation of these to others in the family. By the end of the first year 967 (85%) of the children remained in the investigation; 44 had died, and 125 had removed from the city. In only 6 instances had coöperation been lacking. The study is now in its fourth year. The main object of pursuing it for eight years is to study the familial pattern of disease, particularly respiratory conditions. It is already apparent that the intrafamilial method of clinical investigation yields a simultaneous view of infectious disease—notably subclinical varieties—in other members of the family which could not otherwise be studied. Regular tuberculin testing is revealing exact information about the tuberculisation of the group.

From this work Spence has already drawn the broad conclusion that over-emphasis on diagnostic medicine diverts attention from the detailed study of the sequence of clinical events that make an illness, and that a scientific study of this sequence of events, minutely observed and carefully recorded, is the method of the natural scientist which becomes a powerful instrument in the training of the young clinician Such a broad approach to the study of life—particularly child life—is like a breath of fresh air in these days of ultrascientific medicine when many students, and their teachers, cannot see the wood for the trees

BEDPAN EXERCISE

As a labour saving device the bedpan is a total loss Patients have known this all along, and the news is now reaching the doctors, and even a few of the hospitals Dr J G Benton, Dr Henry Brown and Dr H A Rusk[1] have lately been measuring the energy expended by patients on the bedpan and comparing it with that expended on the bedside commode They studied the oxygen consumption of patients in these two situations by means of a closed circuit metabolism apparatus Since there were psychological and other obstacles to the study of patients during actual defæcation, the subjects were asked to " bear down " 10 times when seated first on the bedpan and later, after a rest, on the commode The tests were conducted in a small quiet room and the patient was screened off from the doctor, who could nevertheless observe him through a crack Of the 28 patients studied 15 had cardiac conditions, and the remainder were either normal or had other disorders The tests showed that in all patients there was a consistently greater oxygen consumption for performance on the bedpan than on the commode, and that there was no improvement with practice The rise above resting levels was, in the cardiac patients, 50 7% higher on the bedpan than the commode, and in the other subjects 48 4% This finding confers the blessing of science on the universal opinion of those who have used a bedpan If we wish to spare patients, and especially cardiac patients, we will give them a bedside commode, if we wish them to use half as much energy again we will insist on the bedpan

NEUROLOGICAL COMPLICATIONS OF DISSECTING ANEURYSM

With dissecting aneurysms of the aorta neurological *involvement is not uncommon, and its presence may* help in diagnosis In 1944 Weisman and Adams[2] described 11 confirmed cases of dissecting aneurysm with prominent neurological dysfunction This was associated with ischæmic necrosis of the peripheral nerves, the spinal cord, or the brain With necrosis of the peripheral nerves the circulation through the main artery of the limb was impeded, with a pulseless cold extremity, weakness, anæsthesia, and loss of tendon reflexes When the blood supply of the spinal cord was affected a transverse lesion of the cord developed rapidly, with flaccid paralysis, sensory impairment up to a spinal level, and loss of sphincter control Impairment of the cerebral blood supply resulted in hemiplegia often accompanied by confusion, stupor, or coma, and at times a " carotid hemiplegia " with blindness on the side opposite to the hemiplegia Weisman and Adams showed that the cause of the neurological disturbance was either extension of the dissection into one of the major branches of the aorta (such as the common carotid artery) with occlusion of the lumen, or severance of the smaller branches of the aorta by the dissection, this was the commoner cause of interference with the blood supply of the spinal cord Moersch and Sayre[3] have analysed the Mayo Clinic records of 26 verified cases of dissecting aneurysm. Clinical neurological signs were present in 12, but probably this does not truly reflect the incidence of neurological complications, since 9 other patients died so suddenly that neurological examination was impossible. They found ischæmic lesions of the spinal cord and brain but no convincing evidence of peripheral nerve lesions

These studies indicate that dissecting aneurysm of the aorta is a possible diagnosis when a sudden cerebral or spinal disturbance is associated with other symptoms such as severe pain in the chest or abdomen, perhaps radiating to the back It is of historical interest that probably the first recorded patient with a dissecting aneurysm and cerebral involvement was King George II who " was found fallen on the ground, speechless and motionless,"[4] and in whom post mortem examination showed a dissecting aneurysm of the ascending aorta

ANIMAL OR VEGETABLE?

For some of us the true tragedy of Kongwa lies not in the sad loss of £36 million but in the harm that the failure may do to other projects which demand something more than a parochial outlook on food problems We are told there is nothing so shy as a million dollars, and a million dollars once bitten can be expected to be twice shy There are others who feel the most recent reduction of the meat ration as another tragedy It is useless to point out to such people that they have available, often quite cheaply, abundant supplies of animal protein in such forms as milk, cheese, fish, and the rabbit or hare. For them " protein " means a pre 1914 steak

Things being as they are, the Nutrition Society could not have chosen a more topical theme for its symposium in London on Jan 20 than the comparative merits of animal and vegetable foods Problems relating to the supply of food have a fascinating complexity As D A Boyd showed, cost in money, man power, and acreage must be balanced against the value of the foods as sources of energy, protein, vitamins, and " waste products " which can be utilised to provide more foods. By setting the balance more correctly, we are now producing for human consumption nearly twice as much vegetable food as before the late war Animal products have also been increased in total amount, despite large reductions in imported feeding materials The dairy cow, which needs little protein in its diet because it can synthesise amino acids in its rumen, is largely responsible for this increase K L Blaxter has calculated that the cow can take, from cereal, residues of which a high proportion are inedible by man, and manufacture from them, and yield in its milk, enough lysine to make up for the shortage of this amino acid in the original cereal The cow needs much attention, but repays the extra *cost of labour by the high value of its produce* Other creatures such as the hen need even more attention, and, as K J Carpenter pointed out, must be provided with rations rich in well balanced protein Such a diet is usually costly, but the cost can be reduced by the skilful mixing of proteins from different sources This is what we do for ourselves when we insist on a " good mixed diet " G R Tristram showed that many plants, if they were eaten entire, would provide at least a good mixture of amino acids It is the specialised organs such as the seed which have the incomplete mixtures

If the protein in the diets of newly weaned children is inadequate the syndrome of kwashiorkor, or malignant malnutrition, may appear Dr Lucy Wills has obtained excellent results by treating this disease with large amounts of the protein of dried skim milk Cow's milk and other agents reported to cure the disease may act by virtue of their specific amino acids or the vitamin B_{12} which all of them probably contain. Some experimental and theoretical evidence which supported this concept was advanced by Dr. R. F. A. Dean. He has fed children with mixtures of soya and various cereals, and is convinced that diets could be constructed exclusively from plant sources, on which young children could grow rapidly and remain healthy. His mixtures lacked vitamin B_{12}; he has found that the addition of this improves their nutritive value for rats, and it would probably improve their value for children. The mixtures were given their original scientific trials by Miss Harriette Chick, who suggested that many similar mixtures had great possibilities, especially in child nutrition. Even protein-free extracts of some plants have, it seems, remarkable powers of supplementation when added to plant proteins.

The meeting demonstrated the broad range of the modern science of nutrition. Scientific knowledge is often many years in advance of its application to human purposes. Do our administrators and their financial advisers realise that in nutrition the need to apply our knowledge is urgent?

TOO FEW BEDS

THE London Local Medical Committee has published a resolution urging "that in view of the amount of illness at the present time, unprecedented since the start of the National Health Service, and the consequent increased need for hospital accommodation in London for acute cases, every step should be taken to provide beds by all possible means." Among the means suggested are exclusion from hospital of normal maternity cases, postponement of non-urgent operations, and temporary crowding of wards.

Certainly the incidence of sickness is now unusually heavy. Dr. Frank Gray, secretary of the committee, points out that one in three of the cases offered to the Emergency Bed Service is not admitted to hospital. This is a serious matter, though fortunately the chances of getting a patient admitted are better than this ratio suggests, since the doctor commonly makes arrangements directly with the hospital; indeed the service is only provided as a means of helping doctors when direct approach has failed. Inquiry of the service shows that in the first week of January applications for admission of acute cases were 32% higher than at the start of last year. There were 1792 applications, with 1058 admissions; the number admitted is actually greater than in the same week of 1950, owing, no doubt, to the gradual increase in the number of staffed beds. During the same week the service received 571 applications for admission to infectious disease hospitals, and about the same proportion were admitted. This is the first time since the start of the N.H.S. that there has been any serious difficulty in gaining admission for patients with infectious diseases. This difficulty is due primarily to the unusually high prevalence of infectious diseases, and notably of measles; but probably it is due also in part to the recent appropriation of infectious disease hospitals for general use.

Except for the closing of maternity wards to normal confinements, the remedies suggested by the London Local Medical Committee are already being put into operation. The regional boards have called for a reduction in the intake of cases from waiting lists, and many hospitals have spontaneously started crowding their wards. Whether in the long run this is a wise step remains doubtful. In some large hospitals it has an evil reputation, and the gain in the numbers of nursing staff achieved through determination not to overwork nurses should not lightly be endangered. Perhaps by next winter criteria for definite stages of emergency could be worked out, at each stage a definite degree of overcrowding would be called for, and this would equally definitely be cancelled as soon as the emergency passed. Such a system would ensure that the willingness of nurses was not exploited unnecessarily.

RELIEF OF POSTOPERATIVE PAIN

THE anæsthetic used to be the worst part of having an operation, but now the focus of dislike has changed to the postoperative period. Pain, particularly after abdominal and thoracic operations, is the worst feature of this period, and its relief must be a first concern. The favourite remedies are morphine and its synthetic substitutes (which were discussed in our leading article last week), but their value is sometimes offset by such undesirable side-effects as respiratory depression and vomiting. Many alternatives have been suggested; two very promising ones are intravenous procaine and intravenous alcohol. With each of these two methods, however, careful supervision is necessary if overdosage is to be avoided. Now Blades and Ford[1] suggest another rather novel method of relieving postoperative pain, which they have used successfully after thoracotomy —an operation commonly followed by severe pain. Fine plastic tubes made of 'Aeroflex' are placed along the edge of each of four ribs bordering the incision. The tubes are held in place with a few fine sutures, and the end of each tube is brought out at the anterior angle of the wound. Through these tubes, 2 ml. of procaine solution is injected every two to three hours. At the same time morphine is given, if necessary, for its euphoric effect. These workers are convinced that the procaine injections produce very great and hitherto unobtainable relief. Pain disappears immediately after the injection, and the patients are able to move about in bed; and earlier ambulation is possible. The tubes are left in situ for nine days, and the wounds heal well and without infection.

MR. BEVAN AND MR. MARQUAND

THE new Minister of Health, unlike Mr. Aneurin Bevan, will not be a member of the Cabinet. Some may welcome this as evidence that the health services are being taken out of politics; but in the next few years, when Defence will demand an increasing share of the national resources, we may have cause to regret the loss of influence that Mr. Bevan's departure entails. Mr. H. A. Marquand, however, may prove an able advocate of efficient medical care, and he comes to the Ministry at a time when a fresh mind and a conciliatory disposition can do much good. His chief task is to improve the balance of the service by giving more weight to the needs of public health and general practice—if only because failure to meet these needs is partly responsible for the strain on the hospitals. As will be seen from the brief biography we print on p. 243, he brings to these problems a valuable experience not only of economics but of human relations and of social services; and he has won approval at the Ministry of Pensions. It remains to be seen whether the N.H.S. will gain or lose by the removal of housing from the control of the Minister of Health. When a change of this kind has been debated and resisted for years it is somewhat irritating to have it made overnight, to facilitate a Cabinet reshuffle, and without detailed consideration of the consequences. As has been sensibly suggested, a logical sequel to the present changes might be the union of the Ministry of Health with the Ministry of National Insurance in a Ministry of Social Services—over which Mr. Marquand (elections permitting) would be well qualified to preside. Meanwhile, he has more than enough on his hands without asking for more. The medical profession will earnestly wish him success in what he has to do.

A SOCIOMEDICAL STUDY OF TWO HUNDRED HOSPITAL MEDICAL PATIENTS

JOHN PEMBERTON
M D Lond , M R C P
SENIOR LECTURER IN SOCIAL MEDICINE,
UNIVERSITY OF SHEFFIELD

THE following study was undertaken with two general aims (1) to find out how a random sample of teaching hospital medical outpatients and inpatients fared after discharge from hospital, and (2) to assess what part environmental influences had played in the ætiology of their illnesses The wards and outpatient department concerned dealt with all general medical illnesses except diabetes

METHODS

It was decided to try to obtain detailed sociomedical records of 100 outpatients and 100 inpatients To this end, a letter was sent to an unselected consecutive series of 146 outpatients and 144 inpatients, whom I had examined one year previously, asking them to come to the hospital for a follow up examination In the case of inpatients who had died in hospital, the letter was sent to the nearest relative In response to the letter, 100 outpatients, 88 inpatients, and near relatives of 12 inpatients who had died came to the follow up clinic. The distribution of the commoner diagnoses among the 47 outpatients and 43 inpatients who failed to attend was similar to that among the patients who were investigated, except that 9% of the non attenders had cancer compared with 1% of those who attended, and 7% of the non attenders had pulmonary tuberculosis compared with 1 5% of those who came

Each patient who attended the follow up clinic had a consultation lasting about three quarters of an hour The diagnosis was reviewed, the outcome of the illness assessed, and a detailed account of the social environment obtained This included an occupational history since leaving school, details of economic status, diet, housing conditions, leisure activities, and a family history The patient was also asked about his childhood, his married and working life, and an attempt was made to assess the quality of his more important human relationships The interviews were conducted in private, and all but one or two of the patients willingly gave all the information required I was often impressed by the additional light thrown on these medical cases by privacy and adequate time To supplement the case history, a relative was interviewed separately in 29 cases, in 8 cases a visit to the home was made, and in 10 cases the patient's place of work was inspected

TABLE I—DISTRIBUTION OF THE 290 PATIENTS BY AGE AND SEX

—	Years							
	0– %	10– %	20– %	30– %	40– %	50– %	60– %	70 + %
Male (161)	0 6	3 7	13 0	20 0	27 3	19 9	13 0	2 5
Female (129)	0 8	7 7	14 7	26 4	22 5	17 0	8 5	2 4
Total (290)	0 7	5 5	13 8	22 8	25 2	18 6	11 0	2 4

GENERAL PICTURE OF MEDICAL ILLNESS IN A TEACHING HOSPITAL

Age and Sex

For this part of the analysis, the 90 patients who failed to attend because of death or some other reason have been added to the 200 who attended, thus making a consecutive unselected series The whole group contained 144 inpatients and 146 outpatients The age and sex distribution of the group is shown in table I

Diagnosis

Table II shows the diagnoses of the 290 patients. The commonest illnesses found, including cases with multiple diagnoses, were peptic ulcer and non ulcer dyspepsia* 23%, psychoneurosis 13%, pneumonia, bronchitis, and bronchiectasis 8 3%, essential hypertension (including its complications such as cerebral thrombosis) 8 2%, rheumatic heart disease 4 8%, rheumatoid arthritis 4 1%, and pulmonary tuberculosis 3 1% The primary diagnoses were classified under the following headings

TABLE II—DIAGNOSES OF THE 290 PATIENTS

Somatic		Psychosomatic		Psychoneurotic	Psychotic	Multiple diagnoses
Rheumatic heart disease	12	Peptic ulcer	33	28	Schizophrenia 1	10
Cancer	11	Dyspepsia	33		Suicide 2	
Bronchitis emphysema and pneumoconiosis	9	Essential hypertension (including coronary disease 4 cerebral thrombosis 1, malignant hypertension 1)	23			
Pulmonary tuberculosis	9	Rheumatoid arthritis	11			
Nephritis	5	Asthma	8			
Lobar pneumonia	4	Nervous diarrhœa	5			
Bronchiectasis	3	Spastic colon	4			
Pernicious anæmia	3	Rheumatism	4			
Thrombophlebitis	2	Thyrotoxicosis	4			
Hydronephrosis	2	Ulcerative colitis	2			
Tænia saginata	2	Migraine	2			
Cirrhosis of the liver	2	Fibrositis	5			
Miscellaneous (single cases)	30	Epilepsy	2			
		Miscellaneous (single cases)	7			

	Somatic %	Psycho somatic %	Psycho neurotic %	Psychotic %	Multiple diagnoses %
146 outpatients	18	57	17	1	7
144 inpatients	46	41	4	1	8
290 all patients	32	49	10	1	8

These categories tend to merge into each other, but it was considered worth attempting to separate them to obtain a clearer idea of the ætiology of the different illnesses

For grouping the psychosomatic cases, Halliday's classification (1943) was largely adopted and his definition used as a guide "a bodily disorder whose nature can be appreciated only when emotional disturbances—i e., psychological happenings—are investigated in addition to physical disturbances—i e , somatic happenings." The most important diseases included in the psychosomatic group were peptic ulcer and non ulcer dyspepsia, essential hypertension, "rheumatism," spastic colon, nervous diarrhœa, ulcerative colitis, and hyperthyroidism The psychoneurotic group included those patients whose symptoms consisted mainly in a morbid degree of anxiety and who showed no evidence of a physical disorder

The dominating importance of psychosomatic and psychoneurotic illness in current medical practice was confirmed in this series of cases

Duration of Illnesses

Table III shows that approximately four fifths of the 200 patients who attended the follow up had had symptoms of their illness for more than a year before coming to hospital A third had had symptoms for five years or more

---

* Non ulcer dyspepsia covers patients referred to the hospital as possible cases of peptic ulcer in whom there was no radiological evidence of ulcer and no reflex cause of dyspepsia such as chronic cholecystitis

TABLE III—DURATION OF SYMPTOMS BEFORE COMING TO HOSPITAL IN THE 200 WHO ATTENDED

—	Years					
	0–1	1–2	2–3	3–4	4–5	5 +
100 outpatients	17	29	15	1	3	35
100 inpatients	23	31	5	8	3	30

Results of Treatment

It is perhaps inaccurate to describe the health of a patient a year after receiving treatment recommended at a hospital as the result of that treatment His improvement or deterioration in health is often due to more potent causes The patient's present condition was assessed mainly on his own and, where possible, a relative's report, unless these conflicted with the results of physical examination If a new complaint had developed, this also was recorded The so called results of treatment are tabulated in table IV

It will be seen that in the whole outpatient group, 17% were assessed as cured, 48% improved, 24% about the same, 7% worse, and 4% dead In the inpatient group, the figures were 22% cured, 31% improved, 16% about the same, 11% worse, and 20% dead Perhaps the most significant finding was that about three quarters of all these patients still had their original complaint, they had neither died nor been cured of it Of the 200 who attended, 36 had developed a new complaint Three quarters of these 36 patients had passed from one psychosomatic or psychoneurotic complaint to another, a point which was made by Ryle (1939) in the Goulstonian lectures on the visceral neuroses It seems that in many illnesses the "disease" is a necessary component of the patient's adaptation to his environment and to get rid of the disease either the "patient as a person" or his environment must be changed

TABLE IV—RESULTS OF TREATMENT IN THE 200 PATIENTS WHO ATTENDED AND THE 53 WHO REPLIED BY LETTER

—	Cured	Improved	Same	Worse	Dead	New complaint
% of 128 outpatients	17	48	24	7	4	16
% of 125 inpatients	22	31	16	11	20	13

RELATIONS BETWEEN ILLNESS AND SOCIAL ENVIRONMENT

The results of treatment of many of these medical illnesses were disappointing The detailed inquiry into the social history was undertaken to try to ascertain the contribution to the ætiology of the illnesses made by environmental and hereditary influences and the extent to which the illnesses might have been prevented by healthier living conditions

Often, of course, it was impossible to assign an environmental or hereditary cause to the illnesses with any certainty In a good many cases a combination of more than one environmental cause, with or without an inherited susceptibility, was no doubt responsible Environmental conditions to which especial attention was paid were occupation, housing, nutrition, the use of leisure, and human relationships Table V shows the cases in which one of these factors seemed to be of dominant ætiological importance

Unhealthy occupational conditions were judged to be the main cause of illness in 5 5%, bad housing conditions in 3 5%, inadequate diet in 0 5%, misuse of leisure in 1 0%, and unsatisfactory human relationships (in which inherited disposition may have been an important factor) in 43 5% There were no cases of known hereditary disease, but in 9% of the cases hereditary factors were considered important ætiologically In 46%, there was no *apparent* environmental or hereditary cause of the illness If anything, the numbers assigned to each main ætiological category have been underestimated, for only the more obvious cases were included

Occupation

The 11 cases in which the patient's occupation was judged to be the chief cause of the illness are shown in table VI All but 1 were men The exception was a woman who developed lead poisoning on taking up war work at the age of 65 There were 4 cases of silicosis or miner's pneumoconiosis, 3 of chronic bronchitis and emphysema, 2 of gastric ulcer, and 1 of dyspepsia

TABLE V—ENVIRONMENTAL AND HEREDITARY INFLUENCES AS MOST IMPORTANT ÆTIOLOGICAL FACTORS

—	Occupation	Diet	Housing	Leisure	Faulty human relationships	Heredity	No apparent environmental or hereditary cause
100 outpatients	6	0	2	1	52	0	39
100 inpatients	5	1	5	1	35	0	53
Total %	5 5	0 5	3 5	1 0	43 5	0	46

Diet

Only 1 case in the series was obviously due to a deficient diet The patient was a bachelor, aged 60, who had scurvy He had given up work about six months before and did his own cooking on a gas ring in the single room where he lived He did not bother to cook any vegetables

There may have been other cases in this series where a poor diet was an important ætiological factor, in some of the infective illnesses perhaps, in the 12 cases of rheumatic heart disease, or in the 9 cases of pulmonary tuberculosis Without an accurate analysis of the diet before the onset of the illness it was impossible to assess its importance In 2 cases of dyspepsia the rushed conditions under which the meals were eaten seemed to be important

TABLE VI—OCCUPATION AS CHIEF CAUSE OF ILLNESS

Sex	Age	Diagnosis	Occupation
F	65	Lead poisoning	Painting Poor cleansing facilities
M	44	Miner's pneumoconiosis	Coalminer (ripper) for 20 years
M	38	Miner's pneumoconiosis	Coalminer (ripper) for 17 years
M	55	Silicosis and bronchitis	Gannister crusher 30 years
M	65	Miner's pneumoconiosis	Coalminer (ripper) for 19 years
M	55	Chronic bronchitis and emphysema	Coalminer for 21 years
M	55	Chronic bronchitis and emphysema	Hot drop stamper Exposed to dust gases fumes and big temperature differences
M	71	Chronic bronchitis and emphysema	Street hawker
M	34	Gastric ulcer	Foreman responsible for rapid construction of aerodrome runways in early part of the war
M	45	Gastric ulcer	Doing two jobs Police war reserve 8 hours a day and commercial traveller the rest
M	55	Stress dyspepsia	Doing three jobs Coalminer small holding and keeps a shop

TABLE VII—BAD HOUSING AS CHIEF CAUSE OF ILLNESS

Sex	Age	Diagnosis	Housing
F	16	Rheumatic fever	7 sleeping in two bedrooms No bath outside w c damp ceilings falling
F	14	Rheumatic fever	Shares bedroom with her 5 sisters No bath outside w c Damp
M	17	Nephritis	12 sleeping in two bedrooms No bath, outside defective w c
M	10	Bronchiectasis following 2 attacks of pneumonia	Condemned back to back slum house 4 in one bedroom Outside w c
F	12	Acute nephritis	Rural slum house Very damp 11 share three bedrooms Outside midden
M	48	Anxiety state and essential hypertension	Living in his mother s house Wife and mother do not speak to each other
M	25	Nervous dyspepsia	Living in in laws house 10 of them in all

Housing

In 7 (3 5%) of the cases bad housing was considered the chief cause of the illness The diagnosis and housing of these cases are listed in table VII

The homes of the 2 patients with rheumatic fever and the 2 patients with nephritis listed in the table were visited All 4 were overcrowded and insanitary The families were large and a large proportion of the brothers and sisters had had illnesses of the streptococcal or pneumococcal group (table VIII)

One of the patients, a girl, L.M, aged 14 (rheumatic fever), lived in a house which was one of a terrace of four roomed slum houses, about eighty years old The front room opened on to the street and was used as a bedroom by Mr and Mrs M Mrs M who had diabetes and a colostomy following an operation for carcinoma of the rectum, was in bed The floor of the back kitchen had dropped about 2 in below the wainscot and the rain came in above the lintel of the door The water supply to the house was through one slow running cold tap over the kitchen sink and the w c was at the back of the house across the yard In the back bedroom was one bed where the two boys slept One of these also had rheumatic heart-disease In the front bedroom, the six sisters, including the patient, slept in two double beds There were no sheets or pillow cases, no floor coverings and no furniture in the bed rooms other than the beds Each of the rooms measured about 10 by 8 ft The patient and her brother who had rheumatic heart-disease gave a history of repeated attacks of tonsillitis and quinsy

Most of the illnesses in which bad housing was considered the chief cause resulted from infection, but the last two cases (table VII) showed how the psychological strain of crowded housing conditions can aggravate or cause illness

Mr J N, aged 25 (nervous dyspepsia), was living with his wife and one year old baby in lodgings when first seen. The diagnosis was nervous dyspepsia which he had had for about one month His wife was pregnant, and, because of this, they had been asked by their landlady to find other accommodation When seen a year later, he was still getting bouts of epigastric pain The four of them were now living at his mother in law s house with her and his brother in law s family of five There were three bedrooms and an attic He, his wife, and his two children slept in the attic He and the baby's crying got on his mother in law s nerves, and she had told them to leave He went to bed at 7 or 8 P M to get out of the way

This patient was a sensitive conscientious man whose mother had died when he was 3 It is possible that a more robust personality might have remained well in his circumstances, but it is equally likely that if he and his family could have had a house of their own he would not have become ill

Leisure

There were two patients with chronic alcoholism, both of whom had had venereal disease Misuse of leisure might be regarded as the chief cause of their illnesses. In both, however, there were also potent psychological causes

Mr W E, aged 64, lost his mother when he was 10, and his father remarried when he was 17 His father was a heavy drinker The patient acquired gonorrhœa at 17, resulting in his present urethral stricture He became a heavy drinker in early adult life and developed delirium tremens during the pneumonia for which he was admitted to hospital

Mr W L, aged 51, had very strict parents He joined up at 17 in the 1914–18 war and acquired syphilis soon after Had gonorrhœa and has been treated for urethral stricture Discharged from the Army with neurasthenia Has been drinking heavily ever since He is a steel painting contractor and says he is spending £3 10s a day on drink He was in a state of great anxiety about his heart when seen, although, apart from a systolic pressure of 170 mm, nothing abnormal was found He produced the following letter which he said a doctor in another town had given him three years before

> Dear Mr L
>
> I examined you today You are suffering from a serious disease of the heart threatening paralysis You are only fit to do light work if at all
>
> L R C P

This letter had, I think, aggravated his anxiety state

Heredity

There were no cases of known hereditary disease in this series However, 6 of the 8 patients with asthma, 5 of the 28 patients with peptic ulcer, 5 of the 17 cases of psychoneurosis, and the single cases of mental deficiency and psychosis gave a positive family history

TABLE VIII—ILLNESSES OF BROTHERS AND SISTERS OF TWO CASES OF RHEUMATIC FEVER AND TWO CASES OF NEPHRITIS IN WHICH OVERCROWDING WAS CONSIDERED THE CHIEF ÆTIOLOGICAL FACTOR

Rheumatic fever			Rheumatic fever			Nephritis			Nephritis		
Family	Age	Illnesses	Family	Age	Illnesses	Family	Age	Illnesses	Family	Age	Illnesses
James	21	Cervical tuberculosis	Barbara	28	Pneumonia	Annie	12	No history	Ronald	14	Rheumatic fever Abscesses Septicæmia Mastoid (twice)
Mabel*	17	Rheumatic fever	Elizabeth	28		Henry	40		Roy	13	Recurrent tonsillitis
Ernest	15	Pneumonia Bronchitis	Violet	23	Pneumonia	Ernest	38		Cynthia*	12	Nephritis

			Kathleen	2							
			Sister	3	d bronchopneumonia						
			Brother	$^{4}/_{12}$	d wasting						

* Patient

suggesting inherited susceptibility Siblings, parents, cousins, uncles, aunts, and grandparents were included in the family inquiry

Human Relationships

The data about human relationships and ætiology were of necessity largely derived from the patients' own accounts of their lives and illnesses Although it is difficult to present data of this sort quantitatively, it seemed to be worth attempting so that some sort of estimate, however rough, could be made of the contribution of unsatisfactory human relationships to the ætiology of the illnesses A special effort was made to assess the importance of emotional insecurity in childhood and of psychological stress before the onset of the illness

A control group of 81 healthy people was obtained by interviewing random samples of 47 patients from the fracture wards, 7 from a plastic and burns unit, and 27 normal parturient women in a maternity hospital They were not an entirely satisfactory control group The sex and the social class distribution was similar to that of the 200 patients but they were somewhat younger (average age 38 years compared with 42) Also the possibility that a group of accident cases will include more than a normal proportion of psychologically abnormal people cannot be excluded

Insecurity in Childhood

The factors which were considered most important were persistent quarrelling, drunkenness, unfaithfulness, or violence of one or both parents, and the loss at an early age of father or mother by death or separation. The following cases illustrate relatively clear cut examples of insecurity in childhood

TABLE IX—HISTORY OF INSECURITY IN CHILDHOOD

Type of illness	No of cases	Loss of one or both parents before age 6	Insecure childhood for other reasons	Total
Somatic	55	13%	11%	24%
Psychosomatic	109	18%	37%	55%
Psychoneurotic	17	18%	59%	77%
Controls	81	12%	11%	23%

Mr G.S , aged 40 (essential hypertension) Father died when he was 2 Mother remarried when he was 8 Parents separated when he was 14. They were never happy My stepfather used to sleep with a razor under his pillow I was terribly afraid of him If I saw him coming up the street, I would run in and sit quiet as a mouse

Miss D.S aged 31 (rheumatoid arthritis) Mother was in mental hospital father killed in 1914–18 war 'My youth was anything but happy I was brought up in an orphanage. You live in an atmosphere of fear all the time wondering whether you are doing right

Table IX shows the incidence of a history of important causes of insecurity in childhood in the main types of illness and in the control series Loss of one or both parents before the age of 6 was commoner in the psychosomatic and psychoneurotic groups than in the somatic and control groups but the differences were not, by themselves, statistically significant The other causes of insecurity in childhood were commoner in the psychosomatic and psychoneurotic than in the other two groups and the differences were statistically highly significant

Psychological Stress before Onset of Illness

A history of mental stress at, or just before, the onset of illness was significantly commoner in the psychosomatic than in the somatic group—61% compared with 16% (table X) The three most important causes of mental stress at or about the time of onset, which were all significantly more common in the psychosomatic than in the somatic group, were serious illness or death in the family, work anxiety, and sexual or marital difficulties (table X)

TABLE X—HISTORY OF MENTAL STRESS AT, OR JUST BEFORE, ONSET

Type of illness	No. of cases	No with stress at onset	Commonest types of stress at onset		
			Family illness or death	Work anxiety	Marital or sexual difficulties
Somatic	55	9 (*16%*)	3	0	2
Psychosomatic	109	67 (*61%*)	15	28	8

EXAMPLES

Family Illness

B R , aged 11 (recurrent vomiting) Attacks came on, six months previously, during the last illness of his father, and cleared up within three months of his father's death

Work Anxiety

Miss E P , aged 42 (nervous diarrhœa) Duration one year, since new job in administrative department of a big store Dealing with complaints about fuel supplies Got back to her old job as manageress of a shoe department, and the diarrhœa cleared up

Mrs L Z , aged 30 (stress dyspepsia) Mother died at her birth Adopted Foster father drank and foster parents quarrelled Married for ten years , one son aged 7 Husband called up in 1941 She continued to look after their butcher's shop Dyspepsia came on then. " It was a big strain. Husband came home in January, 1946 When she was seen again in May, 1946 her dyspepsia had gone

Marital Unhappiness

Mrs E K., aged 51 (gastric ulcer) Mother died when patient was 3 , stepmother at 8 Father died when she was 11 Patient divorced her first husband because he was unfaithful and drank to excess Her first bout of pain came on at that time Second attack of pain came on just after she lost her home and furniture in 1940 through enemy action She now keeps a theatrical boarding house and gets the pain when she " rushes round a lot

Mrs M.B , aged 51 (toxic goitre) After she had a hysterectomy in 1943, her husband stopped having intercourse with her as he thought her sex life was ended She suspected that he was being unfaithful and symptoms of thyrotoxicosis began to develop

On the limited data available, it was not possible to say whether a particular type of stress was associated with a particular type of illness, but some of the figures were suggestive For example, while only 17% of the 164 patients suffering from psychosomatic or somatic illness gave a history of anxiety arising out of employment at the time the illness began, 46% of the 50 cases of ulcer and non ulcer dyspepsia gave such a history

Some of the burdens which seemed to precipitate the symptoms in these ulcer and non ulcer dyspepsia cases were not abnormally heavy, and no doubt many adults experience similar strains without becoming ill Serious cause for chronic anxiety in childhood was three times commoner in the histories of the ulcer and non ulcer dyspepsia group than in the somatic group, and it seems likely that disturbing experiences in childhood had made some of these patients particularly susceptible to stresses in adult life Davies and Wilson (1937) found that in 84% of 205 patients with peptic ulcer the symptoms began soon after some disturbing event affecting the patient's work or finances or the health of his family In a control series of 100 patients with hernia, only 22 gave such a history Davies and Wilson do not mention possible causes of chronic anxiety in the childhood of their patients

Of the 4 women in this series who suffered from thyrotoxicosis 3 gave a history of marital or sexual anxiety at the time of onset, compared with 8 out of the 109 psychosomatic and 2 out of the 55 somatic cases The figures, although small, suggest that this type of anxiety may be of importance in the ætiology of hyperthyroidism

In general the case histories of this survey support the hypothesis that people who experience chronic anxiety in childhood are vulnerable to psychological stress in adult life and that they are prone to develop psychoneurotic or psychosomatic illness It is difficult to prove that insecurity in childhood and psychological stress before the onset of illness are important causes of the illness, for we cannot demonstrate the mechanism of such a relationship

Some workers have, however, shown that emotional disturbances can produce abnormal physical changes in the tissues Grant and others (1935) showed that urticaria could be provoked through the efferent peripheral nerves when these were stimulated by emotion, and Wolf and Wolff (1943) demonstrated in a patient with a gastrostomy that abnormal physical changes in the gastric mucosa could occur under the influence of fear and anger

CONCLUSIONS

All the cases studied in this survey were seen in a teaching hospital, and, although they were unselected in the sense that all the available cases in one medical service over a given period of time were included, the group was too small and too heterogeneous to be a basis for conclusions of general validity The study does, however, confirm that most medical illness referred to a teaching hospital is long standing or recurrent and that in only a minority of such cases can a cure be expected

It is therefore pertinent to ask how far these illnesses could have been avoided Better conditions of housing, nutrition, and occupation, and a higher level of popular health education, could probably have prevented most, if not all, of the cases of tuberculosis, rheumatic heart disease, nephritis, scurvy, venereal disease, pneumoconiosis, and lead poisoning, which represented about 10% of the total

The striking feature of the series was the high proportion of psychosomatic and psychoneurotic illness—59% of all cases While the bacterial diseases are becoming less important as causes of morbidity and mortality, diseases in which mental and emotional factors are of primary importance demand our attention more insistently Canby Robinson (1944) in a similar study of unselected cases in the medical service of a teaching hospital concluded that " adverse social conditions cause emotional disturbances in over 50 per cent of the patients and are the major precipitating cause of illness in about 36 per cent of the patients "

Halliday (1948) has produced evidence that the incidence of the psychosomatic illnesses is increasing in Great Britain and the United States and that younger age groups are increasingly affected The reported relative freedom of primitive people from neurotic and psychosomatic illness supports the hypothesis that conditions peculiar to Western civilisation are to some extent responsible Gelfand (1948), for example, states that peptic ulcer and coronary disease are rare in the African in Africa, whereas the incidence of peptic ulcer and coronary disease in negroes in some parts at least of America approximates to their incidence in the white population (Lewis 1942)

While a great deal of ill health can be prevented by further improvements in the physical conditions of life, especially those connected with housing and occupation, it is becoming clearer that further substantial advances in preventive medicine will depend as much, if not more, upon improving the emotional and mental environment, especially in childhood

SUMMARY

Consecutive series of 146 medical outpatients and 144 inpatients who attended a teaching hospital were followed up a year later to assess the results of treatment and to investigate possible social causes of their illnesses

Of the 200 patients who attended the follow-up 17% of the outpatients and 22% of the inpatients had been cured The remainder still had their illnesses or had died of them

In 43 5% of the cases the most important ætiological factor in the social environment seemed to have been disturbed human relationships, in 5 5% unhealthy working conditions, in 3 5% bad housing, in 1% misuse of leisure, and in 0 5% deficient diet In 46% there was no apparent environmental or hereditary cause of the illness The combination of emotional insecurity in childhood and psychological stress in adult life seemed to be a common and potent cause in the cases of psychosomatic and psychoneurotic illness

MANAGEMENT OF BATTLE CASUALTIES FROM KOREA

R M Latta
M B Glasg
SURGEON COMMANDER, R N

During the first two months of the Korean war, H M Hospital Ship *Maine* carried some 1850 patients to base hospitals in Japan For various reasons this report of the management of these patients has to be based chiefly on impressions detailed statistics are not available

The actual sailing time from Korea to Japan was in the region of forty two hours , and on some of the trips the patients were on board for about forty eight hours On other trips, because sailing was delayed by typhoons in the neighbourhood, they remained on board for up to six days With few exceptions patients had had primary surgical treatment before embarkation, close to the battle zone and/or at an evacuation hospital In many cases, however, the records were scrappy and some cases had none at all so that it was impossible to learn the time between treatment and admission to the ship, or the kind of treatment given, even if there had been the necessary time and staff to do this on board For obvious reasons follow up of the patients was impossible, but a cross section of similar cases was seen at a base hospital in Japan, and some idea of the probable results of treatment was obtained

Such figures as can be given were obtained from the nominal lists which accompanied each load of patients, and absolute accuracy cannot be assured About 230 cases had major soft tissue wounds without bone involvement, and 180 had major compound fractures , Some 400 had relatively minor wounds for which no special treatment apart from renewal of dressings was required, and no particular mention will be made of this group The figures referring to other types of injuries will be given later under the appropriate headings

In general, the first thing which impressed one was the need of the average patient for food and rest , and considerable improvement was apparent after supplying these two things alone for three or four days Evacuation of the patient from the front line is now organised to such a degree that he gets little chance of resting, and he may even be snatched away from approaching food He goes with little pause from front line to dressing station, dressing station to field hospital, field hospital to hospital train, hospital train to evacuation hospital, evacuation hospital to hospital ship or aircraft, and so, eventually, to base hospital With a fair proportion of patients this itinerary is short-circuited, but those who go through the whole programme arrive travel weary, quite apart from any wound or injury they may have. Moreover, adequate medical supervision is difficult under these circumstances and it is possible that a small number of patients may suffer as a result—e.g., by the development of gas gangrene.

When admitted on board most patients needed only postoperative supervision, and these did very well; but some cases went wrong, and it is chiefly with these cases that this report is concerned.

SOFT TISSUE WOUNDS

Soft tissue wounds comprised the largest group of cases. All had had surgical treatment, and all had been given routine penicillin (the usual dose was 300,000 units of procaine penicillin daily or twice daily), while in some cases an antibiotic bomb of penicillin, steptomycin, and 'Aureomycin' had been used.

Out of the 410 cases of major soft tissue wounds and wounds in which bone was involved, 51 (12%) required further surgical treatment during the short time they were on board. The indications for intervention were the usual ones: local pain, toxæmia, hæmorrhage, unhealthy smell or appearance of the dressing, evidence of gangrene, and so on; but there was a further group of cases in which primary suture had been carried out. In other words, cases in which the surgical treatment had been inadequate or over optimistic required further intervention.

It was abundantly evident that nothing can yet take the place of the efficiently planned surgical toilet of a wound. The trimming of damaged skin edges, opening up of fascial planes, excision of dead or damaged tissues, removal of foreign bodies (especially those of vegetable origin), and hæmostasis are all essential. Of the value of antibiotic therapy there can be no doubt, but it cannot take the place of surgery in the treatment of war wounds. If surgery is efficient, delayed primary suture or secondary closure with or without skin grafting can become almost a matter of routine in conjunction with antibiotic therapy; and it was possible to follow this procedure on board in a small number of cases. If, however, surgery has not been efficient, with larger wounds where there has been a good deal of tissue damage further intervention is required, usually as a matter of some urgency; with less severe wounds the antibiotics limit the spread of infection and the development of toxæmia, thereby permitting some delay in instituting surgical treatment without serious deterioration in the patient's condition. The general appearance of such a wound is rather like that of a cold abscess. It is highly probable that a number of such cases were overlooked on board because they were relatively asymptomatic, and there were always enough cases with symptoms to keep one busy.

The inclusion here of primary suture among the reasons for further surgical intervention is open to criticism, which is valid as long as the limitations of primary suture are recognised. If the wound is treated efficiently and if it can be kept under supervision for the first few postoperative days, primary suture should certainly be considered. But, under the conditions which war imposes, it is not without danger. Front-line surgery cannot always be done under good conditions, and the necessary evacuation of the patient from the front line through the various staging posts to the base hospital means that he is not under surgical supervision all the time. Because of this, primary suture is not without risk. Two minor tragedies were seen in this series. In both cases wounds of the foot had been closed. Had they been left open both patients would probably have had useful feet; but, as a result of closure of imperfectly excised wounds, there was swelling and tension and spread of infection, and it seemed likely that both feet would eventually have to be amputated. These were the two worst cases seen, but almost every wound which had been closed had to be opened and have further excision done.

GAS GANGRENE

There were 3 cases of clinical gas gangrene in this series, involving the legs in 2 and the arm in 1. All 3 had had routine penicillin therapy from shortly after the time of wounding, but primary surgical treatment had not been adequate. In 1 case a mid-thigh amputation was required. In the other case where the leg was involved, there was gangrene of the distal half with proximal extension in the extensor muscle group; by excising this group it was possible to leave enough tissue to justify a below knee amputation. For the case in which the arm was affected, dead and damaged tissue was widely excised and the wound left open in the hope of preserving the limb; but amputation was done later since the loss of structure was so widespread that the limb could never be useful. It is known that despite the general use of antibiotics, gas gangrene developed in cases evacuated from Korea by other methods.

HÆMORRHAGE

For the most part patients were received and disposed of before the time when secondary hæmorrhage usually appears; and, indeed, secondary hæmorrhage should be uncommon if wound toilet has been adequate. Hæmorrhage following primary wound toilet presented a minor problem. In the first place it seems bad for the patient's morale if he can see a spreading patch on his dressing; and secondly, if the operation has been done elsewhere, there always seems to be some (usually quite unjustifiable) concern that damage to one of the larger vessels may have been overlooked. If there was evidence of continued bleeding for a few hours after admission, the patient was taken to the theatre. As a rule, only persistent capillary oozing was found; but in a few cases there was a definite bleeding point.

There was one patient with fairly profuse continued bleeding from a wound just below the level of the knee-joint on whom three attempts to stop the bleeding had been made before admission. The fourth attempt, done on board with a rather wider exposure than had been used before, showed that a circle of cortical bone about 1 in. in diameter, had been chipped off the anterior upper end of the tibia. In this case hæmostasis was secured with Horsley's bone wax; in other cases ligation of a bleeding point, firm pressure with hot packs, or the application of Oxycel gauze was effective. Diathermy was unfortunately not available.

It was noticed that in several cases the method used to control hæmorrhage at the time of primary operation was to plug the wound firmly with a gauze or soft-paraffin gauze pack. This was effective as far as control of bleeding was concerned, but it interfered seriously with the policy of leaving the wound open, and the plugs had to be removed at the first opportunity. Sometimes, too, the dressings over such wounds were fixed in place with encircling turns of adhesive plaster, which naturally soon became tourniquets. The relief to the patient by dividing this strapping was most noticeable.

It was surprising how often the line of the missile crossed the anatomical line of the main vessels of a limb without involving them. When the major vessels appear to be in the line of fire there is more than one method of dealing with the case. If the wound leads directly to the vessels and there is serious loss of blood, the surgeon has no alternative but to ligate them if repair is impossible. If, on the other hand, there has been no great loss of blood judging by the patient's condition, and the wound track does not expose the vessels, then it may be advisable to leave them undisturbed and hope for the eventual formation of a traumatic aneurysm or arteriovenous fistula which can be dealt with later when the collateral circulation is established But it seems doubtful whether this second policy can wisely be applied to the femoral artery in the lower third of the thigh or to the popliteal artery for in these areas the formation of a hæmatoma will tend to obstruct by pressure any collateral channels

3 cases were seen in which the distal third of the femoral artery had been damaged The wounds, produced by sharp nosed, high velocity missiles, were small and did not obviously involve the vessels The patients were first seen on board with a tense swelling round the lower thigh with ascending gangrene of the leg, and all required mid thigh amputations In 2 cases this was done on board , the 3rd is mentioned later in more detail It would probably have been wiser to explore for possible vascular damage at the time of primary surgical treatment, and, having found it, to ligate the damaged vessels, and to rely on a paravertebral block or reflex dilatation to encourage opening up of the collateral channels This area of the body is notoriously bad for vascular injuries , and, because of tension, there seemed in these cases to be no possibility of the reserve channels opening up

With regard to amputations, these were done, whenever possible, at the site of election Skin flaps were cut, although sometimes the position of the original wound necessitated slight modifications of the usual anterior and posterior flaps In infected cases the flaps were brought loosely together over gauze , in the others primary closure was done, leaving a rubber drain in for two or three days

WOUNDS COMPLICATED BY COMPOUND FRACTURES

Fractures, generally, were treated in padded plasters, and if there was no real complaint they were left alone The criteria for further intervention were the same as for soft tissue wounds Adequate wound surgery is, if possible, even more important than when bone is not involved, and the remarks about the treatment of soft tissue wounds apply here with equal force

The standard plasters were used for femurs a pin through the upper end of the tibia incorporated in a plaster spica was the routine method of fixation, although in the early days a Tobruk splint was commonly used Handling the patient was much easier when the splint was used, but it did not give the same degree of immobilisation and, therefore, of comfort to the leg No attempt was made to check radiologically the position of the bone ends , if the limbs were of equal length and the contours were approximately the same, the position was accepted as adequate until the patient could be given definitive treatment With regard to plasters in general, two points seem worth making

The first is that it is desirable, under the circumstances described here to split the plaster as soon as it is applied This had not been done with the first patients carried, and it was almost always necessary to do it , it is much easier to to do this at the time of application than later, on a conscious apprehensive patient with a swollen limb Later on, plasters were being split , but the division must be in the whole length of the plaster, and it should also include any bandages which have been used to fix dressings in place before the plaster was applied

The second point is that there is a case for the routine description on the outside of the plaster shell of the injuries underneath preferably using a rough sketch One patient arrived on board without any notes He had a laparotomy wound, and a silent abdomen , and he was in a left hip spica which had been extended to include the right thigh There was nothing to show that this extension concealed a wound of the right thigh which, as it happened, involved the right femoral artery The patient did not complain particularly of this leg , he was toxic, but this was thought to be due to the paralytic ileus which he had , and the first indication of the true state of affairs was gangrene of the foot It is just possible that with a little extra attention his leg might have been saved , as it was, it had to be amputated

INTRATHORACIC WOUNDS

82 patients with thoracic or thoraco abdominal wounds were carried There were 2 deaths in this group All combinations of pneumothorax and hæmothorax, both unilateral and bilateral, with and without injury to the lung, were observed All these patients had been treated before embarkation , but the majority of them were in an unstable state and required careful and constant supervision Most of them arrived on board with one or more intercostal catheters connected to water sealed drainage bottles These catheters, usually of 12 or 14 F size, were not efficient drainage tubes

Possibly, with continuous gentle suction they might have proved satisfactory , without this they quickly became blocked with fibrinous clots Unless continuous suction is available, a tube of much wider bore is required As a routine the catheter was removed except in those rare cases where there was drainage, and we relied on intermittent aspiration of the chest with a syringe On one occasion removal of the catheter was followed by the rapid escape of 17 oz of serosanguinous fluid which had been dammed back

Pneumothoraces were released by using an intercostal needle attached to a water sealed drainage bottle No attempt was made to aspirate air , it was considered adequate if the intrapleural air pressure was reduced to atmospheric pressure Whenever possible radiological control was used , but for technical reasons it was impossible to use the X ray apparatus while we were at sea, and it was necessary to depend largely upon clinical findings for deciding when to aspirate This was, of course, not satisfactory , for, while almost all the patients showed some improvement judging by their increased comfort, loss of apprehension, and increased exercise tolerance, the clearance of the pleural cavities was delayed and a greater number of thoracotomies would probably be required at a later date

The common emergency was tension pneumothorax

Sudden development of this in a patient who had been comfortable with no cyanosis or dyspnœa on slight exertion was very alarming It was found that a readily available water seal drainage apparatus was an M R C giving set connected to the air inlet tube of an M.R C bottle In one patient who suddenly developed acute dyspnœa, a needle connected to this device was put into the lower part of the chest, and 3 pints of blood were literally pushed out in twenty minutes by the tension of the air above the hæmothorax Oxygen was tried in many cases of thoracic injury but it was found that the only patients who really appreciated it were these chest emergencies, who clutched the B.L B mask as though it was a lifebelt

Of the 2 patients who died, 1 had a left hæmopneumothorax with collapse of the lung This had been aspirated but the lung had not yet re expanded He suddenly developed a tension pneumothorax on the opposite side, and despite early release of this died of asphyxia The other case was of bilateral hæmopneumothorax with a valvular opening on the anterior chest wall In addition, this patient had severe jaundice, probably of infective origin His hæmothorax persisted despite drainage, aspiration, and vitamin K therapy

ABDOMINAL INJURIES

Of the 40 patients with abdominal injuries, 3 died All were in the postoperative stage, apart from 1, on whom a colostomy was done for rectal damage which, reasonably enough, had been overlooked

As in the other groups of cases, there were many about which there was little or no information It was found, however, that this was only a theoretical disadvantage, and that clinically the cases could be divided into two principal groups those in which bowel sounds could be heard, and those with a silent abdomen If there was any doubt the case was put in the second category , for, early in this series, the doubtful patients were given a trial period on a limited fluid intake by mouth, and a few showed fairly serious deterioration. Because of pressure of other work, it was not possible to observe closely these doubtful cases, and it seemed safer to treat them as being worse than they possibly were.

It was assumed that patients with silent abdomens had a true paralytic ileus following peritoneal contamination or infection, and not a postoperative or traumatic ileus. Routine treatment with gastric suction and intravenous fluids was given. A Levine's tube was preferred to Ryle's because of its slightly bigger bore; the Miller Abbott tube was not used, since a paralytic condition was being dealt with. At first, intermittent aspiration with a syringe was carried out. Later, continuous suction using the two bottle siphon method was applied, and this proved much more satisfactory and efficient. It was difficult to keep a check on blood-chemistry, but a theoretical fluid and chloride balance was worked out daily for each patient, and during the short time they were with us, this was apparently satisfactory. It is unfortunate that intravenous glucose, which can be given almost ad lib., is so much more likely to irritate the wall of a vein than is normal saline, which has to be rationed.

All the patients in this group were given routine penicillin and streptomycin with large doses of vitamin C. In the absence of definite information about dates of operation, it is difficult to make a statement about the healing of wounds, but my impression is that this was delayed. Of 14 colostomies which were opened, it was thought advisable to use a Paul's tube in 3, for it appeared that sealing off of the peritoneal cavity had hardly begun by the third or fourth postoperative day. In another 3 cases large abscesses containing upwards of 4 oz. of thick pus were opened through the laparotomy wound. Since these discharged satisfactorily they were not explored, but they appeared to originate intraperitoneally. A feature of them all was that they were almost asymptomatic, and they were obvious chiefly because of their size; it seems likely that the antibiotic therapy had something to do with this.

About 12 cases in this group had damage to one kidney, and in all but 2 the injured kidney had been removed. All those on which a blood urea estimation was done showed a level of over 100 mg. per 100 ml., and urine output was not satisfactory, though this could have been related to an inadequate postoperative intake. They were given a controlled, gradually increasing fluid intake with a glucose basis, and they all did well.

Of the cases in which the damaged kidney was not removed 1 was admitted with a blood urea level of 180 mg. per 100 ml. and the level rose to 250 mg. per 100 ml. in the next two days, after which the patient died. Intravenous glucose and isotonic sodium sulphate were both administered but they did not influence his condition in any way.

The other case in which nephrectomy had not been done had on admission oliguria with a blood urea level of 150 mg. per 100 ml. Intravenous glucose produced no response, but there was a temporary increase in urine output after administration of 1 pint of sodium sulphate. This improvement was not maintained and anuria gradually supervened.

It seems possible that these were 2 cases of reflex anuria, and that primary nephrectomy might have saved them, but on admission they were too ill to withstand operation.

A few cases of wounds of the bladder and urethra were seen.

HEAD INJURIES

Of the 19 patients with head injury, 2 died. One arrived on board unconscious and died without regaining consciousness; no notes were available, but it seems likely that he had severe damage to his basal ganglia. The other had a compound fracture of the skull which had been operated on; it is thought that he had a septic encephalitis. The other cases were of compound fractures of the skull, which had been operated on, and these did well on restricted fluids (2 pints daily) and fairly continuous sedation with intramuscular paraldehyde or sodium phenobarbitone. Routine penicillin and one of the sulphonamides were given.

BURNS

Of 19 cases of severe burns, 2 died. The majority were petrol burns, and most of them had resulted from using petrol to light fires. The value of protective clothing was obvious, and the inflammability of the mechanic's working dress was demonstrated only too clearly. Treatment consisted in gentle cleaning with cetrimide ('Cetavlon') and saline, followed by dusting with penicillin sulphonamide powder and dressing with soft-paraffin gauze, padding, and a pressure bandage.

With extensive burns, even when it appeared that a satisfactory pressure dressing had been achieved, the amount of leakage through the dressings was surprising and almost alarming; and blood, plasma, and electrolytes had to be infused fairly quickly. Frequent blood checks were required. In the 2 fatal cases the necessary fluids were probably not given fast enough. It would seem that there is still a place for coagulation therapy on extensive flat surfaces in an attempt to cut down fluid loss.

INTRAVENOUS THERAPY

A good deal of practical experience in intravenous therapy was obtained, though control by blood chemistry observations was less exact than was desirable.

The equipment used was the standard M.R.C. apparatus; but reserves had to be obtained from American sources, and it was found that the different parts of the two types of sets are not readily interchangeable. It seemed that the M.R.C. equipment was easier to supervise, though this may have been only because of familiarity, and all fluids of American origin were transferred to M.R.C. bottles. This was usually done in the laboratory; but occasionally, when an emergency arose it had to be done in the ward. No complication followed this potentially dangerous manœuvre.

Blood.—Fresh blood was taken from the ship's company as required, but supplies were also obtained from an American blood bank. For some reason which was never discovered, this stored blood did not run easily through the M.R.C. apparatus, although there was no difficulty with fresh blood. Eventually, as a routine, each pint of stored blood was diluted with a similar quantity of saline, and the resulting mixture gave no trouble.

Plasma.—Although dried plasma is supposed to keep indefinitely, the available stocks which were of 1942 and 1944 vintage were for the most part, unfit for use. This may have been due to ineffective sealing of the bottles; but it is perhaps worth mentioning that dried plasma obtained from American sources was marked with a date of expiry.

Technique.—A supply of small bottles containing 10 ml. of sterile isotonic sodium citrate was kept in each ward, and this fluid was used to clear intravenous drips which were not running satisfactorily. It is true that small clots may be set free by injecting the citrate under pressure into the giving set; but there was no evidence that this actually happened, and no complication resulted. When the number of available veins is getting small, every means of maintaining the patency of a vein has to be used. Finally, it is most desirable to avoid inserting an intravenous needle near a joint. The patient should be free to move, within limits, the limb that is being used for an intravenous drip, more especially if for any reason he is not fully coöperative. Effective splinting of the limb was found to be difficult to secure, and it rather tended to obstruct the free flow of fluid. The most easily accessible veins are those on the forearm; but, if these were not available, we cut down on the internal saphenous vein near the ankle. If one of the veins in the antecubital fossa had to be used, a plaster of paris splint was applied in preference to a prefabricated splint.

Public Health

PERSONAL HYGIENE AND THE SPREAD OF DISEASE

I H J Bourne
M B Lond
GENERAL PRACTITIONER, HORNCHURCH, ESSEX

It has often been suggested that the virus of poliomyelitis may be transmitted by fæces, certainly they are the source of infection in some other diseases, notably gastro enteritis My aim here is to show that such infections, and possibly poliomyelitis too, can be spread as a result of faulty personal hygiene in lavatories

Poliomyelitis virus has been found in the fæces of healthy adults in five out of six households where a case occurs (Pearson and Rendtorff 1945) Burnet (1940) points out that the high incidence of infection in infants is always associated with an abundant source of virus in the environment, excreted in the fæces by adults and older children

THE MODE OF TRANSMISSION

If lavatory fitments could be incriminated as factors in transmitting the virus from person to person, light might be thrown on the mystery of epidemic spread of poliomyelitis, as well as on the transmission of gastrointestinal infections

The crimes of serving and eating food, and washing up, with unwashed hands are so common, and so hard to combat in large communities, that they come to be tolerated even by those who have fought to eliminate them Printed injunctions, supply of washing facilities, personal supervision by a responsible officer—all these wax and wane because of human frailty The battle is still being waged by our public hygienists, and is foremost in all pamphlets advising on the prevention of disease

There is a general aversion to such unhygienic activities as sharing eating utensils, towels, and shaving mugs Moreover, the man in the street in most countries is increasingly aware that epidemic disease may spread via contaminated hands, food, water, or milk All the more surprising, therefore, is the world wide existence of a " blind spot " *in the toleration of modern lavatory* routine

SOME CURRENT PRACTICES

Ideally, a person entering any lavatory should find a wash basin, soap, and clean towel provided, in addition to equipment which is often disinfected, and a clean seat towel Hygienic toilet paper should also be provided In many conveniences in offices, restaurants, and shops neither paper nor washing facilities are supplied Even in public lavatories supplied by local health authorities a charge is made for the use of washing facilities—if they are provided at all In the home, even the best of small children do not wash carefully unless supervised It is worth considering the conditions in some primary schools Within ten minutes of school opening the closets are turned into a hygienist's nightmare The seats, chains, and handles become soiled with excreta Any infective organism could be transferred from these places to the hands of other users of the same closet The time elapsing between visits would be very short, especially in the rush hours of morning break and lunch time In summer the germ might not cool sufficiently to be destroyed it could remain viable for some time

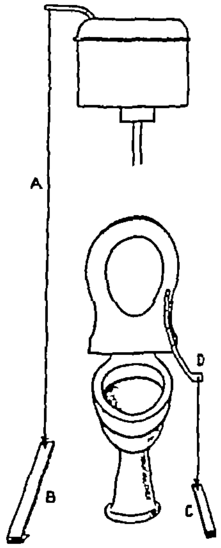
FOOT CONTROL OF CLOSET APPARATUS

Even in a perfectly equipped lavatory it is possible for a user to leave with germ contaminated hands, in spite of conscientious washing An infected person may touch not only the articles mentioned, he may deposit infected material on the door handle, door lock, door surface, the hand-taps, the soap container, the paper box Thus it is easy to feel a false sense of security

Malten (1946) has described a foot operated flushing system A simple foot lever is fastened to the floor and the chain lengthened to meet it Dr Malten points out that many people use the chain rather than the handle He therefore encloses the adaptor chain in a metal gas pipe fastened to the wall Incidentally he refers to the increase of threadworm infection during the " soapless war years "

Foot control being an advance, it is reasonable to apply it to water tap manipulation, to the raising or lowering of the lavatory seat, and to door control Many hospitals are fitted with foot operated wash basins In future such fitments should be made compulsory in lavatories The door could be closed after entry and fastened by an automatic spring catch at floor level, by means of a foot release mechanism it could also be made to swing open automatically, and remain ajar This would allow the occupant to leave without handling the door It is noteworthy that in New York doors are not considered necessary in some public lavatories

There are several practical advantages in foot control First it conforms to generally accepted principles of hygiene and æsthetics Then the cistern lever is less liable to strain and damage, because the foot pedal descent is checked by the floor Sanitary engineers might well devise new models in which the only visible parts need be foot-buttons projecting through the floor to operate the cistern and the seat Existing systems can be adapted immediately by a handy man equipped with wood, screws, hinges, and a length of chain, as shown in the illustration By this device children are spared the problem of how to reach the chain, and adults are spared the consequences of some of the solutions they commonly find for this problem.



The hand chain is replaced by a long chain (A) which connects the cistern lever to one end of a wooden pedal (B) The other end of the pedal is hinged to the floor The lavatory seat is shown in the raised position This is achieved by stepping on the wooden pedal (C), which is attached by a short chain to a lever (D) made of 5-ply wood.

Even if it be generally conceded that such a reform is desirable, the changeover to foot operated closets is likely to be gradual Meanwhile some other devices should help us to attain a measure of safety Paper can be used to cover and handle the seat, and paper towels for individual use can be obtained A bowl of chlorinated water would be an asset as a hand steriliser in closets and kitchens Sellers of soft fruit should use scoops where possible, and cooks should use ladles and servers

I wish to thank Dr Charles Wilcocks, Dr J Gorman, and Dr P X O'Dwyer for their help and advice, and Mr D Chaffey for help with the illustration

Influenza

In the great towns of England and Wales deaths from influenza increased from 458 in the week ended Jan 6 to 890 in the week ended Jan 13—the largest increment in the last twenty years Pneumonia cases and deaths, and influenza deaths, in the great towns during the seven weeks up to Jan 13 were as follows

	Week ended						
	Dec 2	*Dec 9*	*Dec 16*	*Dec 23*	*Dec 30*	*Jan 6*	*Jan 13*
Pneumonia							
Cases	282	347	374	364	503	956	1300
Deaths	198	236	289	351	383	770	982
Influenza deaths	28	34	33	54	102	458	890

Totals for the great towns during the first two weeks of this year, compared with the corresponding period in the preceding two years, are as follows

	1949	*1950*	*1951*
Pneumonia			
Cases	1237	1189	2256
Deaths	799	509	1752
Influenza deaths	87	99	1348

For the whole of England and Wales notifications of primary and influenzal pneumonia in the seven weeks up to Jan 18 were 497, 573, 684, 647, 962, 1774, and 2538

The bulk of the increase in influenza deaths has occurred in the Northern and North-Western regions, as is shown by the following summary of the incidence of deaths from influenza per million population in the great towns grouped regionally

Region	*Week ended* Jan 6	*Week ended* Jan 13
Northern	83	91
North Western	63	138
London and South Eastern	11	21
Others (average)	5	13

Of the 890 deaths from influenza in the great towns during the week ended Jan 13, 85% were of patients over 55 years of age The total for each age group is as follows under *1* year, 12 , *1–15*, 4 *15–25*, 3 , *25–35*, 7 , *35–45*, 33 , *45–55*, 75 , *55–65*, 156 , *65–75*, 277 , *75* and over, 323

Pneumonia cases and deaths notified in the great towns have increased proportionately much less than influenza deaths Deaths from pneumonia and influenza have been relatively very numerous in the great towns in the more northerly regions and especially in Liverpool In the week ended Jan 13 Liverpool suffered more than any of the other great towns of 949 deaths in the city during this week 216 were attributed to influenza and 214 to pneumonia (Prof W M Frazer, the medical officer of health, is reported[1] to have said that an average weekly figure for deaths in the city at this time of year was 200)

Though the incidence of influenza is increasing throughout the country, it seems that no situation has developed elsewhere comparable to that in the North and North-West , in London and the rest of the country the disease is comparatively mild, with some more intense localised outbreaks

Claims to Sickness Benefit—In England and Wales new claims to sickness benefit under the National Insurance Act numbered 370,500 in the week ended Jan 9, compared with 233,400 in the week ended Jan 2[2] For the guidance of people claiming sickness benefit whom the doctor cannot see without some delay, the Ministry of National Insurance has issued advice in the following terms

> To avoid loss of benefit a person who is prevented by illness from working should give the local National Insurance Office written notice of incapacity within the first three days This notice is normally given on the First Medical Certificate (MED 1) issued by the doctor when he first attends the patient , but where exceptionally the patient has not been seen by the doctor within the first three days, a note written by or on behalf of the patient is accepted as notice Where notice has been given without a medical certificate, the formal claim on the doctor s First Medical Certificate should follow as soon as the doctor has been seen, and in any case within ten days of the start of the illness Patients who have to give notice without a medical certificate should give their full name and address and their National Insurance number If they are claiming an increase of benefit for wife or other dependant details should be given If the doctor s examination has been delayed and he wishes his certificate to cover any earlier period of incapacity he can give a supplementary certificate (MED 5) or he can make a suitable note in the ' remarks space on the first medical certificate

Influenza Abroad—The situation in Europe was reviewed last week (p 168) Influenza is now prevalent also in Finland, where cases have been shown to be due to the A prime strain In Spain, as in Holland, there is evidence that the disease is due to virus A

Last week W H O issued the following comment

> ' The fact that in 1949 influenza was more prevalent in European countries other than Scandinavia and Britain leads one to think that the contrary will happen this year, and that regions so far spared this winter will remain less seriously affected Latest information indicates a decrease in the number of cases observed in Copenhagen and Oslo Research indicates that the virus causing the current outbreak belongs to type A Neither the spread nor the severity of the influenza epidemic now prevalent can be compared with the more serious epidemics which occurred in the first part of the century So far complications are rare and the mortality rate remains very low Influenza is now present not only in Europe The World Health Organization has also been notified of outbreaks in Hawaii and Japan, while the disease has made its appearance in Canada and the United States as well "

Smallpox at Brighton

Up to noon on Jan 22 there had been no notifications of smallpox outside the Brighton area The total number of cases notified (uncorrected) is 30, and there have been 9 deaths With 2 exceptions the recent cases have been in contacts under surveillance In view of the occurrence of a suspected case at Crowborough, Sussex, it would be premature to state that all the sources of infection in Brighton are known or that the end of the outbreak can be foreseen The need for special vigilance continues throughout the country

Poliomyelitis

In England and Wales notifications of poliomyelitis during the week ended Jan 13 were paralytic 27 (37), and non-paralytic 11 (10) total 38 (47) These figures represent a decrease in notifications of 9 compared with the previous week, for which the figures are given in parentheses

Notifications in the corresponding week of the previous four years were 1947, 16 , 1948, 49 1949, 37 , and 1950, 50 The notifications in the second week of 1951—38—are therefore well below those for the corresponding week in 1948 and 1950 These three years are comparable in that they followed years of very high prevalence

Births and Deaths in 1950

In England and Wales the provisional stillbirth-rate and infant-mortality rate for 1950 were the lowest ever recorded The Registrar-General reports[1] that the stillbirth-rate was 22 6 per 1000 total births and the infant-mortality rate 29 8 per 1000 live births, compared with 22 7 and 32 4 in 1949 The birth-rate was 15 8 per 1000 population, compared with 16 7 in 1949 , and the death-rate was 11 6 per 1000 population, compared with 11 7 in 1949

Public Health

PERSONAL HYGIENE AND THE SPREAD OF DISEASE

I H J Bourne
M B Lond
GENERAL PRACTITIONER, HORNCHURCH, ESSEX

It has often been suggested that the virus of polio myelitis may be transmitted by fæces, certainly they are the source of infection in some other diseases, notably gastro enteritis My aim here is to show that such infections, and possibly poliomyelitis too, can be spread as a result of faulty personal hygiene in lavatories

Poliomyelitis virus has been found in the fæces of healthy adults in five out of six households where a case occurs (Pearson and Rendtorff 1945) Burnet (1940) points out that the high incidence of infection in infants is always associated with an abundant source of virus in the environment, excreted in the fæces by adults and older children

THE MODE OF TRANSMISSION

If lavatory fitments could be incriminated as factors in transmitting the virus from person to person, light might be thrown on the mystery of epidemic spread of poliomyelitis, as well as on the transmission of gastro-intestinal infections

The crimes of serving and eating food, and washing up, with unwashed hands are so common, and so hard to combat in large communities, that they come to be tolerated even by those who have fought to eliminate them Printed injunctions, supply of washing facilities, personal supervision by a responsible officer—all these wax and wane because of human frailty The battle is still being waged by our public hygienists, and is fore most in all pamphlets advising on the prevention of disease

There is a general aversion to such unhygienic activities as sharing eating utensils, towels, and shaving mugs Moreover, the man in the street in most countries is increasingly aware that epidemic disease may spread via contaminated hands, food, water, or milk All the more surprising, therefore, is the world wide existence of a " blind spot " in the toleration of modern lavatory routine

SOME CURRENT PRACTICES

Ideally, a person entering any lavatory should find a wash basin, soap, and clean towel provided, in addition to equipment which is often disinfected, and a clean seat towel Hygienic toilet paper should also be provided In many conveniences in offices, restaurants, and shops neither paper nor washing facilities are supplied Even in public lavatories supplied by local health authorities a charge is made for the use of washing facilities—if they are provided at all In the home, even the best of small children do not wash carefully unless supervised It is worth considering the conditions in some primary schools Within ten minutes of school opening the closets are turned into a hygienist's nightmare The seats, chains, and handles become soiled with excreta Any infective organism could be transferred from these places to the hands of other users of the same closet The time elapsing between visits would be very short, especially in the rush hours of morning break and lunch time In summer the germ might not cool sufficiently to be destroyed it could remain viable for some time

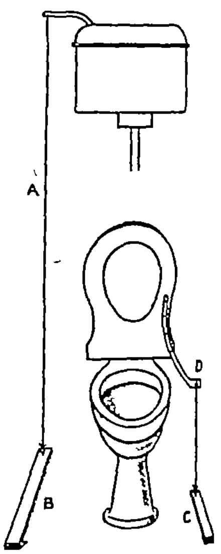
FOOT CONTROL OF CLOSET APPARATUS

Even in a perfectly equipped lavatory it is possible for a user to leave with germ contaminated hands, in spite of conscientious washing An infected person may touch not only the articles mentioned, he may deposit infected material on the door handle, door lock, door surface, the hand taps, the soap container, the paper box Thus it is easy to feel a false sense of security

Malten (1946) has described a foot operated flushing system A simple foot lever is fastened to the floor and the chain lengthened to meet it Dr Malten points out that many people use the chain rather than the handle He therefore encloses the adaptor chain in a metal gas-pipe fastened to the wall Incidentally he refers to the increase of threadworm infection during the " soapless war years "

Foot control being an advance, it is reasonable to apply it to water tap manipulation, to the raising or lowering of the lavatory seat, and to door control Many hospitals are fitted with foot operated wash basins In future such fitments should be made compulsory in lavatories The door could be closed after entry and fastened by an automatic spring catch at floor level, by means of a foot release mechanism it could also be made to swing open automatically, and remain ajar This would allow the occupant to leave without handling the door It is noteworthy that in New York doors are not considered necessary in some public lavatories

There are several practical advantages in foot control First it conforms to generally accepted principles of hygiene and æsthetics Then the cistern lever is less liable to strain and damage, because the foot pedal descent is checked by the floor Sanitary engineers might well devise new models in which the only visible parts need be foot buttons projecting through the floor to operate the cistern and the seat Existing systems can be adapted immediately by a handy man equipped with wood, screws, hinges, and a length of chain, as shown in the illustration By this device children are spared the problem of how to reach the chain, and adults are spared the consequences of some of the solutions they commonly find for this problem



The hand-chain is replaced by a long chain (A), which connects the cistern lever to one end of a wooden pedal (B) The other end of the pedal is hinged to the floor The lavatory seat is shown in the raised position This is achieved by stepping on the wooden pedal (C), which is attached by a short chain to a lever (D) made of 5-ply wood.

Even if it be generally conceded that such a reform is desirable, the changeover to foot operated closets is likely to be gradual Meanwhile some other devices should help us to attain a measure of safety Paper can be used to cover and handle the seat, and paper towels for individual use can be obtained A bowl of chlorinated water would be an asset as a hand steriliser in closets and kitchens Sellers of soft fruit should use scoops where possible, and cooks should use ladles and servers

I wish to thank Dr Charles Wilcocks, Dr J Gorman, and Dr P X O'Dwyer for their help and advice, and Mr D Chaffey for help with the illustration

Letters to the Editor

PROSPECT OF WAR

SIR,—There must be thousands of doctors who would like to join with Professor Penrose and his colleagues (Jan 20) to press, as doctors, for the healing of the world-wide disease of war, if they could but see their way But, like so many of our fellow citizens, we are afraid of being "misled by quasi communism" (*Manchester Guardian*, Jan 19) or playing some other enemy's game if we so much as toy with the idea of negotiation from equality instead of striving after what may well be a receding illusion of "negotiation from strength"

Our political leaders dissect recent history as if it gave us the clue to everything Even so the Power that negotiated from strength at Munich lost the subsequent war, following the historical pattern that it is usually the stronger Power that attacks—and gets beaten (Quincy Wright *Study of War*) It is ingenuous too to assume that, because appeasement at Munich failed to prevent war, the reverse must either have succeeded then or be the golden rule for all the future There are many ways of going to the devil, and among nations challenge and armament must have proved at least as reliable routes as appeasement has ever done *Facilis descensus averno*

The attitudes of peace are positive attitudes Doctors need not become politicians to proclaim to the world that it is their habit to treat foreigners as human beings Whatever their ideology the dose is the same We can go on and attempt to recall politicians and journalists from their frenzies of hatred to the solid need of all men everywhere to be treated as equals, or at least as similars, whether they are misled by Communists, led by Socialists, or guided by capitalists And, like sick men, the sick nations of the world need peace and quiet, an end of past irritations, and a period, not of feverish activity, but of absolute rest for inflamed parts

Finally, could not some international medical or medicolegal congress meet and commend to governments the need for, and the conditions of, a peaceful regulation of our lives? It seems an infinite pity that the conditions of world wide law and order are known to international lawyers today and yet can still be so deliberately flouted by every sovereign State as such

Edinburgh RANYARD WEST

SIR,—Much as I sympathise with all appeals for reason and peace, I am bound to say that last week's appeal by seven doctors to their fellow doctors in this country to do "all in their power to halt preparation for war and to bring about a new and determined approach to the peaceful settlement of disputes and to world disarmament" seems to be wrongly addressed

These seven doctors are opposed to the policy of the Government and the Opposition in preparing for the defence of democracy against the onslaught of totalitarianism They are certainly entitled to their views, and they have (and should have) every right to express them But when they explain to British doctors that "willingness to cooperate and to understand the other man's rights and needs are hallmarks of civilisation" they are stating only a truism, as long as they are not able to produce evidence that Czechoslovak (or Hungarian or Polish) doctors are likewise free to express the same opinions and to oppose the governments of their country in the same way Willingness to cooperate and to understand the other man's rights and needs *are* the hallmarks of civilisation, but precisely because doctors in Czechoslovakia and other countries are forbidden to show any willingness to coöperate, and because they are denied any chance to understand the other man's rights and needs, the world is once more at the cross roads The danger of war is—as it was just over a decade ago—the consequence of dictatorship and not of the belated willingness of the democracies to defend themselves and the right to understand the other man's rights and needs "Cet animal est bien méchant! Quand on l'attaque, il se défend"

BOHEMICUS

SIR—For some time I, and many of my young colleagues, have been oppressed by an overwhelming sense of shame and disgust at the apparently defeatist attitude of the medical profession towards the senseless drift to a Third World War We have waited impatiently for responsible medical men to raise their voices in protest, and until last week we had waited in vain Our wait was not altogether passive and we have attempted often to give a lead albeit unsuccessfully

The signatories to the letter "Prospect of War" have to some extent relieved this sense of oppression and shame May I say, therefore, that I wish to associate myself wholeheartedly with the sentiments they have expressed and their appeal to fellow doctors

London N W 6 JOHN Z GARSON

SIR,—It is becoming increasingly obvious that politics and medicine together are undergoing a shift to the left An already incongruous commensalism is being changed into a more virulent parasitism Presumably in the end politics only will be remaining

It was all the more alarming to see the rate of this change so exposed in your last issue, when political propaganda was allowed to invade the columns which have hitherto been spared for medicine, under the title "Prospect of War"

If such political missionaries "feel compelled to express themselves publicly" again may I, Sir, suggest it be in a special supplement, in limited edition, distributed only to those who express a wish for it?

Woking D W S SHELDON

SIR,—As one of the many liable to early recall to the Forces should hostilities break out again, I should like to express my appreciation of the comments on this subject by Professor Penrose and his colleagues It seems to me that some recognition of the dangerous international situation is no more out of place in a medical journal than it is in any other publication, the more so as doctors would be expected to play a greater part than ever before in any future war On the contrary, such references merely reflect the growing concern of all sections of public opinion over the present catastrophic drift to war

It is not my intention, however, to try to turn your columns into a political forum Rather would I content myself with applauding the increasing preoccupation of men of science with world affairs and hoping that they may thereby recognise their own responsibility in this respect Such interest in the past might have gone a long way to averting previous disasters

As yet, however, there is no organised movement in this country to make known the views of responsible scientific workers, medical or otherwise, on this matter, so vital to us all The United States, however, is a jump ahead of us for in 1949 a group of American scientists formed a Society for Social Responsibility in Science, one of whose main objects is to resist the increasing military and political encroachment on human knowledge and scientific research This body includes many eminent men of science, doctors among them, in its membership roll, and I consider that we could with profit follow its lead, if only to show that all eminent scientists in this country are not Communists or fellow travellers It takes greater courage to form such a progressive movement in present day America than it would here in Britain, but as yet we have had no lead from our own eminent men of science As of all professions Medicine should stand

In England Now

A Running Commentary by Peripatetic Correspondents

In our first house-jobs we owe a great deal to the tactful guidance of that fine body of women, the ward sisters I have never ceased to wonder at the apparently implicit faith with which, later on, they gracefully accept our instructions But in recent years they have fought and lost the battle for beef-tea against its commercial substitutes "Is he eating?" I used to ask, and sister would reply, "Yes, Doctor, I'm very pleased with him today, he took a little beef-tea" Years of facial grimaces and firm remonstrance have been needed to convince them that the goodness of the meat is not in the brew but in the dustbin

Now, when we doctors have almost won this battle, I am faced as a pædiatrician with a new engagement It concerns the latest method of dealing with premature infants I can feel the almost personal animosity aroused by my sadistic action Can there be a more cruel and heartless beast than I, who would starve a newborn baby—a baby weighing only $2^1/_2$ lb For years the first flavour that such babies tasted has been the gentle warmth of Cognac brandy "And now," I can hear one sister saying to another over their private cup of tea, "these so called specialists, who a few years back couldn't tell a nappie from a kaolin poultice, give us orders that not even diluted milk must pass their lips for two, three, or sometimes four days" It will be a long battle this time, calling for eternal vigilance, even in the early hours of the morning, with every probationer, every student nurse, a potential enemy

* * *

Now that attention has been called to Mr S Potter's omission of doctors from his great works, *Gamesmanship* and *Lifemanship,* I shall certainly be swamped with requests for some account of my own painstaking (and -giving) investigations on Doctorship, Patientship, and Nursewomanship Though my results are not yet codified, I am therefore publishing these preliminary notes

1 *Doctorship* is defined as getting one up on the patient without actually killing him One need not say much more in a medical journal, since any doctor who has survived even a fortnight in general practice must have acquired a detailed knowledge of the more important ploys

2 *Patientship* is getting one up on the doctor without actually invoking the General Medical Council or committing suicide In its highest form this often passes unrecognised until the surgery door is closing and the doctor senses that he is not entirely master of the situation Only then will it dawn on him that he has been the subject of a Patientship Ploy—too late for any effective counter-ploy An example of this technique is the Name Ploy Many doctors, in the interests of dignity, adopt a double barrelled name An elementary patientship ploy is to ignore the first part and address the doctor by the second, and often more vulgar, name—thus Dr Fotheringay-Smith and Mr Beauchamp Jones become simply 'Dr Smith" and 'Mr Jones" This ploy is effective only against general practitioners and newly established consultants The experienced consultant will retort with the equally simple counter ploy of expressing gratification at the single name as a sign that his fame is now so great that identification by the first name is no longer needed A variation on this ploy, suitable only for the most senior Patientmen, is mispronunciation of the doctor's name This works best if the name is unusually flamboyant On one occasion my friend Hopking was greeted on his admission to hospital by the genito urinary surgeon, a Mr Leigh-Kerr, with 'Ah! Good morning, Hopkins" He replied "Hop*king*, please, Mr Leaker," and the next day was given the only single-bedded ward in the hospital

Fildes Priestley based the gambit since known by his name on the hypothesis that nothing rattles a doctor worse than a hint that he is ailing Certainly few doctors could withstand Fildes-Priestley's own hearty greeting of "Hello, Doc, you *are* looking tired these days" Another approach, favoured by J Grenfell, is to interrupt the doctor's history-taking with "And how's the doctor himself? Nobody asks after *his* health" The most advanced Patientmen sometimes embroider this ploy with technical terms, but these are apt to rebound if not absolutely fresh My distinguished friend, J Hopking, usually scored heavily by stepping up to his doctor, examining his conjunctivæ, and remarking "Hm, ha A little anæmic, I see, Doctor" But on one occasion he was met by the counter ploy of "Yes, I was badly let down by that fallacy in my student days Nowadays students learn in their first term that only hæmoglobinometer readings can be relied on On the Sahli scale my Hb is 105%" Because of this danger D Sharp prefers the simpler ploy of addressing his doctor as "Sir," in tones implying reverence for advanced years rather than respect for professional attainments.

3 *Nursewomanship* is defined as getting one up on the doctor and/or the patient (but preferably both) without actually marrying either An additional and important aspect of Nursewomanship consists, of course, in the Anti-Sister and Contra Matron Gambits

The leading exponent of Nursewomanship in the London region tells me that her basic ploy is to confess frankly, in full detail and at great length, to doctor, patient, and sister alike, every mistake she makes (except of course the fatal ones) In this way she attains a position where she can lead, so to speak, from strength

* * *

What doctor is not a good driver, and what doctor has not had a motor-car accident? After a late Sunday morning round I sipped coffee with the theatre staff, vowed I was going away till next year, and went out to my car in the snow I had intended to walk to the hospital that morning, for the snow was deep and the roads treacherous, but a farewell remark of my wife's that she supposed I'd be as late home as usual had made me quietly change my mind Now, eager to spring a surprise, I left for home

The drive, as it twists and turns through the hospital grounds, passes through a narrow one way defile, carefully protected by two blind corners I had passed the worst part and was moving on to the open road beyond when I espied our elegant medical registrar, preoccupied and even later than I, heading for the hospital as fast as his A40 would go Fascinated, I just had time to remark to myself, "If he's not careful there will be trouble," when I realised I was in the direct line of the trouble Tooting valiantly and drawing in to the side, I then sat spellbound as he applied his brakes on the ice and catapulted with a crash against the door of my car

We both alighted, both smiled sickly smiles, and both realised that our car was out of action for at least three weeks, that our no claim bonuses had gone with the wind, and that we would both be late home for lunch

Returning sheepishly from telephoning our respective wives, we found the impacted cars surrounded by a team of gleeful surgical registrars who, having critically examined and photographed the remains, advanced some colourful theories on the cause of the disaster Finally, turning their energies to good account, they disimpacted the cars, pushed them to safety, and declared the accident an excellent excuse for a further party

Trudging home later, I reflected that Sunday should indeed be a day of rest, that our medical registrar was really too conscientious for a physician, and that the time had come for me to apply to the Regional Board for *danger money*, if only to offset the projected cuts in car allowances and the 'loading" for specially risky occupations which any insurance company would hereafter add to my premiums

* * *

Could you alter my little girl's certificate, please, doctor? The club man called today and said if she'd broken her arm she'd have got 10*s* a week, but as she's fractured it she'll only get 5*s*

* * *

Aphorism of the Week

Tonight's mystery may be solved by tomorrow's otorrhœa

I think that Mr Stansfield and Mr Drabble are very weeping in their condemnation of cervical incisions, hese, when carried out carefully, can only be of benefit n the Ayrshire unit, with over 1900 confinements per annum, an average of 3 cases each year have been delivered by this method, without any maternal mortality, and the convalescence after vaginal delivery is still in the main more comfortable than after abdominal operation

It would appear from the criteria quoted by Mr Stansfield and Mr Drabble that many of the complications indicating extraperitoneal section are manufactured by ourselves in our maternity hospitals and could well be treated by transperitoneal section, with the one rare exception I have indicated

Ayrshire Central Hospital,
Irvine
RICHARD DE SOLDENHOFF

A C T H

SIR,—In his article last week Dr Morris says that adrenocorticotropic hormone (A C T H) is unlikely to be present in normal blood This opinion is based upon the observation that intravenously administered A C T H cannot be detected in whole plasma after 20 minutes and that multiple divided doses are more efficacious in therapeutic use

It is likely that Dr Morris's review was written before the publication of Bornstein and Trewhella's paper[1] on adrenocorticotropic activity of acid acetone extracts of plasma I have confirmed this work, such extracts are active in the ascorbic acid depletion test of Sayers, Sayers, and Woodbury[2]

In my opinion therefore, adrenocorticotropic hormone is normally present in plasma, and the observations referred to above could be interpreted as indicating a rapid turnover rate of the hormone

Department of Chemical Pathology
King's College Hospital Medical
School London S E 5
D M V PARROTT

SIR,—In Dr Morris's review, two very important contributions to the chemistry of the formation of the cortical steroids have not been considered Dr Morris states that it is likely that secretion of both the "glycogenic" and "mineral" cortical hormones is under the control of the pituitary In view of the fact that all the so called "glycogenic" hormones affect sodium metabolism[3] this division appears rather arbitrary and will confuse an already difficult subject

Pincus et al[4] have shown that 11 desoxy compounds are oxygenated in the 11 position by perfusion through the surviving adrenal gland Also Zaffaroni et al[5] have been able to identify 17 hydroxycorticosterone and corticosterone in the adrenal vein blood of dogs It is significant, too, that, although desoxycorticosterone has been well known for such a long time, apart from one unsubstantiated claim it has never been found in biological material This is of the utmost importance for it has been previously shown that the injection of 17 hydroxy corticosterone leads to sodium excretion[3] and the injection of corticosterone to sodium retention[3] although both have considerable "glycogenic" effects[6]

We thus agree with Dr Morris that the effect of A C T H on mineral metabolism will depend upon the relative proportions of steroids the adrenals are stimulated to secrete, but consider that the division into "glycogenic" and "mineral" corticoid hormones is undesirable

RESEARCH IN ANTHROPOMETRY

SIR,—The Medical Research Council have appointed a committee on growth and form, under the chairmanship of Prof P B Medawar, F R S, with the following terms of reference

> "To advise and assist the council (*a*) in promoting research on the growth and form of the human body with particular regard to the provision of basic scientific data, including the elucidation of factors affecting the rate of growth of the whole body and of its parts and the establishment of norms of stature and weight for different ages and different sections of the population, and (*b*) in facilitating the application of such data to various practical problems, including such as arise within the field of clinical medicine"

One of the committee's first tasks is to make a review of work in the field of anthropometry The committee would accordingly be glad to have information about current or completed anthropometric surveys, including unpublished records, so as to avoid any unnecessary repetition of work and to ensure, if possible, that use is made of existing material It is believed that there are in existence records of height, weight, and other body measurements which, if analysed, could form the basis for research into growth and development Serial records of the growth of the same children from year to year, as well as measurements which have been recorded over a long period of time, would be particularly valuable

BILE PIGMENTS IN URINE

SIR,—The test for bile pigments in urine described by Mr Ingham (Jan 20) is a test for bilirubin only Much confusion has arisen because of the failure to recognise that there are two main groups of bile pigments occurring in pathological urines—bilirubin and biliverdin on the one hand, and on the other "urobilin" and "urobilinogen," the latter group requiring tests different from those used for the former group The detection of urobilinogen and urobilin may be of great value not only in the differentiation of the various types of jaundice but also in the assessment of the stage and progress of cases of infective hepatitis

VITAMIN B_{12} IN PERNICIOUS ANÆMIA

SIR,—The view has been expressed from time to time that liver extracts contain factors additional to vitamin B_{12} which are necessary for the well being of patients with pernicious anæmia

We have always held that the question whether vitamin B_{12} is an adequate treatment for pernicious anæmia could only be answered after a large number of patients had been satisfactorily maintained for not less than two years In this hospital we have a number of patients who have been on controlled maintenance treatment for many years, various liver extracts having been used Since January, 1950, all patients have been treated by vitamin B_{12}, and we believe that the results of maintaining such a group for one year are of interest

The patients were divided into three groups (1) 37 received 20 µg, (2) 49 received 40 µg, and (3) 58 received 80 µg of vitamin B_{12} ('Cytamen) each month by intramuscular injection Taking a red-cell level of less than 4,000,000 per c mm as indication of relapse none of these patients relapsed Those receiving 40 µg each month showed higher average red cell levels than those receiving 20 µg each month, and those receiving 80 µg each month showed a higher red cell level than those receiving 40 µg each month On the 80 µg dose 98% of the patients showed red cell levels above 4,500 000 per c.mm, and 70% red-cell levels above 5,000,000 per c.mm for Wisdom and Peace I am hoping that Professor Penrose and his colleagues may provide this lead

London N 4 ADAIR GIRBY

SALICYLATE, GENTISATE, AND CIRCULATING EOSINOPHILS

SIR,—The letters from Dr Kelemen and his colleagues [1] and Dr Bertolani and his colleagues [2] prompt us to report some of our results These workers found that the administration of salicylate and gentisate in animals, and of salicylate in man,[1] was followed by a marked reduction in the number of circulating eosinophils This latter phenomenon has been used as an indication of adrenal cortical activity, and is of great interest because of the suggestion that the activity of salicylates may be related to stimulation of the adrenal cortex causing a liberation of corticoid substances which relieve rheumatic manifestations,[3] and also because of the report of a mild Cushing's syndrome produced by aspirin [4]

We have investigated the effect of oral administration of sodium salicylate and sodium gentisate on the number of circulating eosinophils in eight normal healthy subjects after establishing the functional integrity of the pituitary/adrenal cortex system by means of ephedrine [5] No significant depression in the number of circulating eosinophils was observed with plasma salicylate concentrations of up to 30 mg per 100 ml and plasma gentisate levels of up to 25 5 mg per 100 ml Kelemen (personal communication) states that plasma salicylate concentrations of over 30 mg per 100 ml were necessary to produce such an effect, and the work is being continued to include investigation of higher plasma salicylate and plasma gentisate concentrations

VACCINATION AGAINST SMALLPOX

SIR,—However mistaken Dr Killick Millard's views and however pernicious the effect on the public mind when garbled versions of his article are reported in the public press, you are to be congratulated on your wisdom in publishing the article It is a comforting sign that we have not yet reached the state of totalitarian countries which only permit the dissemination of orthodox views on scientific matters The editor's liberal attitude does, however, make it even more necessary that an authoritative statement of the case against Dr Millard's curious reasoning should be published, and I hope this will be forthcoming

Dr Millard's article (Jan 13) is so full of non-sequiturs that a considered reply would necessarily far exceed the limits of a letter, but some passing reflections may be made, his attitude reminds me of old Father William, who persisted in standing on his head Dr Millard's central argument is that while vaccination undoubtedly protects the individual it is detrimental to the community If, on the other hand, he had said that whereas one cannot guarantee that vaccination will protect every individual there is no doubt that a well vaccinated community is protected against smallpox, he would have carried informed opinion with him It is well known that a small proportion of individual men and animals do not respond to vaccination or immunisation by developing immunity and that they may succumb to subsequent infection although the immunised herd as a whole will have acquired adequate protection

Carried to its logical conclusion, Dr Millard's argument could be used to discredit inoculation against diphtheria since it is well known that immunised insusceptible children can act as healthy carriers of the infection and so infect unimmunised susceptible children Does Dr Millard therefore suggest that the strikingly successful campaign against diphtheria should be dropped or that all children should be immunised ?

Incidentally, Dr Millard himself says "I am all in favour of everyone who visits the East being efficiently protected by recent vaccination " It is surely relevant that both last year's Glasgow outbreak and the current episode at Brighton were initiated by this type of person. Does Dr Millard then suggest that contacts of these people should not be vaccinated ? Or perhaps he would advocate that any such people who insist on returning to this country should be kept in quarantine for at least a fortnight because of the unvaccinated state of the population here ?

ADJUVANTS TO STREPTOMYCIN

SIR,—In his paper of Dec 16 on tuberculous meningitis, Dr Cathie cites a report by Dr Kirmse and me regarding the treatment of tuberculous meningitis with streptomycin and 'Promizole' [1] He states that we reported that "13 out of 18 cases appeared to be doing well 3–6 months after treatment had started" and expresses interest in a later report of these cases

In our report table III showed that 8 patients had already survived for 12–21 months, and the remaining 5 for 7, 7, 6, 5, and 3 months Up till now (Jan 4) there has been 1 further death during a relapse of meningitis, leaving 12 survivors of the original 18 cases with a survival range of 45 to 27 months

EXTRAPERITONEAL CÆSAREAN SECTION

SIR,—I read with considerable interest the article of Jan 13 by Mr Stansfield and Mr Drabble

Since 1946 I have done an extraperitoneal cæsarean section in 15 cases, but I find that I am doing gradually fewer each year It is an appealing operation, because of the technical artistry required, but one must not be distracted by this lure With the present array of antibiotics to combat the spread of infection to the peritoneal cavity, the success of the transperitoneal lower segment operation can be assured, and the premier advantage of the extraperitoneal operation has disappeared

In my experience, there is only one type of case where the extraperitoneal operation is required that is where cæsarean section is necessary on obstetrical grounds with the additional complication of a protracted labour with the concomitant severe distension of the gut, and the patient is in poor general condition These cases do extremely well under local anæsthesia and even the risk of spinal anæsthesia can be avoided The greatly distended gut is under the control of the peritoneum, thus avoiding any difficulty when the wound has to be closed The convalescence is also easier and there is, as Mr Stansfield and Mr Drabble state, less postoperative ileus. With incipient shock the tissues can be handled gently and there is no worry about adding to the shock by either general or spinal anæsthesia

I am sorry that the article does not mention the simplest way of doing this operation, and the one which is certainly the easiest to learn—namely, the method introduced by Cacciarelli In this operation a small button hole is made in the peritoneum above the bladder, and, with the finger through this, the vesical peritoneum is dissected off Thereupon, the small opening is closed with a purse string suture, so that the peritoneum is then a closed cavity, before opening the lower segment

4 4 g total proteins 6 0 g per 100 ml van den Bergh reaction direct, positive delayed 1 min , indirect, 4 units Thymol turbidity 1 Cephalin cholesterol positive

On Sept 6 the icterus had disappeared but he complained of intense itching mainly on the soles of his feet

On Sept 12 patch tests were done with 20% P A S solution, with 20% streptomycin solution and with a saline control All three gave a negative reading after 24 hours

Shortly afterwards the man left my care and returned home I understand that he has since made fairly good progress and was doing light work early in November He had had no more P A S

The sodium P A S in this case was at first given in tablets of 0 5 g and from July 31 in 3 g cachets The tablets and cachets had been specially ordered and were fresh; there did not seem to be any possibility of deterioration

The patient denied having ever had a blood transfusion He had had a course of penicillin injections in 1947, and a second course from April 11 to 18, 1950, in which a rash had appeared, though with the help of anti histamine drugs it was possible to complete the injections Neither the patient's doctor nor his partners knew of any case of infectious jaundice in the neighbourhood during the six weeks before his visit to Whitby

The acute feverish illness, with severe headache and erythema, followed in five days by jaundice, may reasonably be ascribed to an acquired P A S sensitivity The eosinophilia of 11% indicates an allergic reaction The alternative of infective hepatitis does not seem likely in view of the clinical findings and the absence of a known source of infection Weil's disease was excluded by the urine examination, and again no source of infection was discovered Serum jaundice may be ruled out since the man had not received any injections within four months of the onset of jaundice

The patient shows a well marked tendency to allergic reactions, illustrated by the rash in his second course of penicillin injections The first reaction to P A S , which appeared nine days after the start of treatment when a total of 80 g of P A S had been given, consisted only of erythema and pruritus The reaction 58 days from the beginning of treatment, when 480 g of P A S had been given, was much more severe The 5 cases of P A S sensitivity already described also show this apparent relation between the severity of the reaction and the amount of P A S administered

In Cuthbert s case where the complications (erythema, fever severe jaundice, and anuria) were the most severe and of longest duration the total of 720 g of P A S was the greatest amount in all that any of the cases had received

The cases of Climie [2] and of Morrison [3] developed fever and erythema only , the former had received 324 g and the latter 308 g of P A S (calculated from the data)

The case of Livingstone and Street [4] had headache and high fever followed by jaundice a macular rash, and finally anuria in severity this was second only to Cuthbert s case , the amount of P A S (560 g) was also the second highest in the series

The case of Scott and McCann [5] developed a macular rash and high fever followed by urticaria and later a mild jaundice 380 g of P A S had been given (calculated)

A common finding in these cases is the absence of vomiting and diarrhœa during the administration of the drug Cuthbert found that cases in which these symptoms are absent usually have a high blood P A S level, and this may be a necessary condition for the development of a severe reaction , further observations are required on this point In the present case, though at times vomiting was a prominent symptom, the patient only vomited once during the 20 days before the severe reaction, when his daily intake of P A S was 15 g , in this period his blood P A S level would have been steadily rising, and it probably reached its highest peak at the time of the reaction

My thanks are due to Dr A C Brown of Ripon, who kindly verified the earlier part of the case record, which was obtained from the patient's own notes , and to Dr K Froome, pathologist to Scarborough Hospital, for his help with the investigations

CORONARY DISEASE AND MODERN STRESS

SIR,—According to Professor Platt (Jan 6) the premises assumed in my article of Dec 23 are "very controversial" He thus includes in this category the statements that there has been "a vast increase in coronary disease during the present century," and that the "malady strikes predominantly men in middle life"

Terminology must, surely, be the cause of my failure to secure these limited concessions Indeed the phrase "coronary disease" is far from satisfactory I resorted to it in the same sense, and for the same reasons, as those given by Dr Morris in his article of Jan 6 My own brief definition was "coronary atheroma and its syndromes." By "coronary disease," therefore, is implied not an isolated pathological entity but two main clinical concepts —those of "angina" and of "coronary thrombosis"— occurring in association with coronary atheroma, clinical "thrombosis" further being accompanied usually by the morbid appearances of infarction, with or without an evident clot Gross coronary atheroma does not alone constitute "coronary disease" That such a finding is common in the absence of any previous indication of angina was mentioned by Osler in his textbook Dr Morris now suggests that coronary atheroma may have become less in recent years, though whether this generality applies to the incidence of premature plaques appearing selectively close to the left coronary bifurcation must be doubtful By contrast "coronary disease" has indeed become more widespread The best evidence for this would appear to be much the same as that which convinces historians that there was a sharp increase of plague during 1665—that is, recorded clinical experience

With this definition the statement that coronary disease affects predominantly middle aged men would appear not unduly controversial In support of the postulate that brain-workers are more threatened than their fellows I quoted the Registrar-General's Decennial Supplement for 1931, which shows a selectively increased incidence among professional people Professor Platt now confronts me with a further excerpt from this treatise

> ' Degenerative disease in the heart affects all classes of males to much the same extent, but whereas amongst men whose social conditions are most favourable it tends to express itself as angina pectoris or coronary disease, at the other end of the scale it tends to take forms described on death certificates as myocarditis or myocardial or cardio vascular degeneration '

This pronouncement, says Professor Platt, renders the occupational figures ' almost meaningless "

So far from discrediting them I maintain that it does much to fortify them Angina pectoris is a good honest symptom, fairly easily recognised, and known to be associated nearly always with coronary atheroma It thus virtually identifies coronary disease Without autopsy the only certified cause of death that can have any value must be founded upon some such reputable clinical grounds If, therefore the term "angina pectoris" appears most often upon the certificates of men whose "social conditions" were "most favourable," is it not reasonable to assume that this is because such people

When the condition of these patients treated with vitamin B_{12} is compared with their previous record under liver therapy, it is found that 3% show slightly lower red cell levels on vitamin B_{12} than on liver extract, 32% show no significant difference, and 65% are distinctly better on vitamin B_{12} than they were on liver therapy Thus a majority of our patients are distinctly better when treated with vitamin B_{12} than they were on liver therapy even though, as shown above, more than half the patients are receiving less than an optimal dose of vitamin B_{12} In the group receiving 80 µg of B_{12} each month, 80% show a higher red cell level than they did on liver therapy

From these observations, therefore, it would appear advisable to give at least 80 µg of vitamin B_{12} at monthly intervals to maintain a red cell level of 5,000,000 per c mm , and it is possible that a larger dose will give still better results There is no doubt in our minds that these patients have been better in every respect since vitamin B_{12} replaced liver therapy

DUAL CAUSE OF RAPID DEATH

SIR,—In his letter of July 15, 1950, Dr I B Morris, pathologist to the Kent and Canterbury Hospital, reports a case of sudden death for which necropsy revealed two possible causes—cerebral hæmorrhage and rupture of the aorta Cases of this kind are important in medicolegal practice In 1867 Skrzeczka called the condition " concurrent causes of sudden death ", but this was not quite accurate, and it was Fischer, of Breslau, who in 1923, at the instigation of Professor Puppe, reviewed a number of cases at the Forensic Institute and chose the title " coincidental causes of death " He distinguished three categories (1) two natural causes, (2) a natural and unnatural cause, and (3) two unnatural causes The fewest cases, he said, occurred in the first category, and this is supported by my own experience, for I have seen but one case in 10,000 necropsies on adults (I am not including a case of bilateral rupture of aneurysms of the common iliac arteries with a massive retroperitoneal hæmorrhage This occurred in a man of 65)

The case I am about to report is unusual in that there was a hæmopericardium, due to spontaneous rupture of the right ventricle, and a large left sided lenticulo striate hæmorrhage which had burst into the left lateral ventricle of the brain According to Huchard,[1] of 259 cases, rupture of the right ventricle occurred in 10 1%, and of the left ventricle in 79 9% This indicates that spontaneous rupture of the right ventricle is relatively infrequent, which makes my case still more unusual These percentages accord with those of most authors who have reviewed a number of cases

A young woman, 32 years old, appeared to be in normal health when he husband went to work early in the morning Visitors during the morning were unable to get any response, and when the room was forcibly entered by the police she lay dead on the floor near a bed At necropsy the body was that of a frail woman , there were abrasions about the outer aspect of the right elbow and about the left eyebrow, and a dry brownish stain round the mouth The scalp and skull were intact A horizontal section of the brain at the saw line of the skull (Vienna method used at this institution) revealed a large left-sided lenticulostriate hæmorrhage which had burst into the left lateral ventricle , no atheroma of the circle of Willis , no injury to brain , some noticeable coning The pericardial sac contained 180 ml of fluid and clotted blood On the anterior aspect of the right ventricle there was a rupture of the wall $^3/_4$ in. long The heart was slightly enlarged and weighed 13 oz The left ventricle showed some hypertrophy , no macroscopic fibrosis There was a moderate amount of atheroma of both coronaries, particularly the right, and at the commencement of the aorta , the lungs were acutely congested and œdematous and weighed 26 oz (right) and 24 oz (left) , the liver, spleen, and kidneys were congested, the bladder and ureters were normal The uterus contained a fœtus of $8^1/_2$ months A complete toxicological examination of the organs was negative There was no hypoplasia of the aorta As the pericardial effusion of blood leads to death within a few minutes—usually, though by no means always, by compression of the heart and large veins—it must be supposed that the cerebral hæmorrhage occurred first

Kehrer in his comprehensive monograph does not mention a case of coincidental causes of death during pregnancy Wenger[3] of Sucre, Bolivia, describes a case of incomplete rupture of the aorta and a large fresh hæmorrhage in the area of the basal ganglions and internal capsule The deceased was 70 years old He says " It seems that such an occurrence has not yet been reported "

ACQUIRED IDIOSYNCRASY TO SODIUM *p*-AMINOSALICYLATE

SIR,—The following case is a further illustration of the reaction to sodium *p* aminosalicylate (P A S) described in your columns by Dr Cuthbert[1] and others

A married man, aged 44, suffering from tuberculous epididymitis and pulmonary tuberculosis, was confined to bed at home in Ripon on June 15, 1950 On June 27 P.A.S. was started in a daily dosage of 7 5 g , increased on July 1 to 10 g The drug was withheld every seventh day

On July 4 the man vomited four times , 'Benadryl,' 50 mg t i d , was given Next day the vomiting had ceased, but there was a generalised erythema with severe pruritus On the 6th he vomited three times , pruritus was still severe, P A S was discontinued On the 7th he felt generally better On the 13th he vomited once at 3 A M , but P.A.S was recommenced with 5 g daily On the 14th he vomited about six times in the night, but vomiting ceased by the 16th On the 23rd the dose of P A S was raised to 7 5 g daily On the 29th the drug was stopped for two days, after which the daily dose was increased to 15 g On Aug 2 he vomited twice in the night The P A S was stopped next day and vomiting then ceased From Aug 4 he was again given 15 g of P.A S daily On the 6th he vomited once From the 9th he was allowed out for half an hour morning and afternoon

On Aug 20 he travelled to Whitby, taking a supply of P A S with him During and after the journey he vomited several times, but walked about a mile in the evening On returning home he felt ill, shivered and had a headache On getting to bed he sweated profusely

When seen on Aug 23, he complained of frequent vomiting and severe occipital headache His skin was flushed and moist with sweat, and he appeared acutely ill , temperature 104°F A generalised rubelliform macular erythema was present No enlargement of the cervical glands could be detected P A S was discontinued, a total of 480 g having been administered Next day vomiting persisted The vomitus at first contained blood clots and later some blood stained mucus On the 25th he felt better and had stopped vomiting He was now afebrile and the rash had faded, but there was a faint icterus, best seen in the sclerotics The liver was enlarged two fingerbreadths below the costal margin and was slightly tender The urine was dark , Gmelin's test showed the presence of bile pigment On Aug 27 his jaundice was slightly deeper, but his general condition had improved, and his appetite was returning There was no desquamation On the 31st there was further improvement, the liver edge was now only just palpable

On Sept 1 the urine was reported on as acid, slight trace of protein, no sugar or acetone few hyaline and granular casts , no red cells, spirochætes, or other organisms, sterile on culture Blood findings were Hb 80% (Haldane), red cells 4,850,000 per c mm , colour index 0 9, white cells 5600 per c mm. (neutrophils 53%, eosinophils 11% basophils 1%, lymphocytes 30%, monocytes 5%) Serum albumin

R M V adds to the picture

Gask was a quiet accurate teacher He was also a strict disciplinarian with a well-developed sense of time When he was on duty it was his custom to go round the boxes and remonstrate with any dressers who were habitually late As a professor he was essentially a devolutionist He always saw to it that all the members of his unit had plenty of work to do and plenty of responsibility And thus he trained many generations of first-class surgeons

Soon after Gask took charge of the unit at Barts he began to invite a distinguished surgeon to take his place for a fortnight each alternate summer Harvey Cushing, Moynihan, Grey Turner, David Wilkie, Max Page were among these professional visitors The comradeship which began at home did not end there and he was the moving spirit and adroit courier who made possible the Pilgrim Surgeons visits in the '30s to European centres of surgery One of his fellow pilgrims recalls how:

> 'With Cuthbert Wallace as the born compere, a visiting team of ten or more teachers worked and played with home teams of medical schools of Western Europe, learning each other's techniques and coining a common currency Gask's staff work was behind all this, and his success as a breaker of barriers has been ascribed to his calm unworrying temperament He saved time and effort by not getting excited He was probably unaware of this but he had an instinctive distrust of enthusiasm in medicine using the word in the sense Monsignor Knox attaches to it in religion.

His close relationship with his colleagues abroad was appropriately reflected in his honorary membership of surgical bodies in America, France, and Italy

Outside his hospital, but within his specialty, lay his work for the *British Journal of Surgery*, which was commemorated in a special issue of the journal last July He was elected to the editorial committee in 1919, and from 1936 to 1947 he was chairman. The birthday tribute to him contains the following passage

> In directing the affairs of the *Journal* Gask showed again his capacity for the quiet and effective management of his fellow men and for the broadminded enrolment of all who could help in forwarding the interests of British surgery "

To this end he arranged for Elliot Cutler, consulting surgeon to the American Forces in Europe, to be appointed to the editorial committee, and later he enlarged it to contain representatives of anæsthetics, pathology, ophthalmology, and industrial medicine, and of the provincial and municipal non-teaching hospitals

He had a great enthusiasm for good clinical records and the follow-up clinic. In Changing Surgery, his presidential address to the Medical Society of London in 1935, he said

> " It is abundantly clear that what the medical profession needs are reliable records It should be furnished with the results of various types of operation performed, and it needs these in large numbers. What is required are statistics of a comprehensive and national character and not merely the figures of a few gifted and energetic individuals

He realised that a satisfactory disease classification was the first requisite, and again he became the catalyst He encouraged Dr Percy Stocks of the General Register Office to see whether a morbidity classification could not be drawn up, out of this developed the Medical Research Council's Provisional Classification of Diseases and Injuries, which was one of the main foundations for the World Health Organisation's International Statistical Classification of Diseases, Injuries, and Causes of Death which was adopted in 1948 Beside his membership of the Medical Research Council, he also served on the Radium Commission and on the council and as a vice-president of the Royal College of Surgeons He delivered before the college Hunterian, Bradshaw, and Vicary lectures, and before the Medical Society of London the Lettsomian lectures on Surgery of the Lung and Pleura. As collaborator for the succeeding editions of his textbook on *Surgery* he had first W G Spencer and later H. W Wilson. His co-author in *Surgery of the Sympathetic Nervous System* (1934) was Paterson Ross who succeeded him in his chair

When war came again in 1939 it was unthinkable that Gask would continue in retirement at Hambledon, growing lilies and sitting on the magistrates' bench, he gladly accepted Sir Farquhar Buzzard's invitation to help with the teaching in the Oxford clinical school which had been established at the Radcliffe Infirmary almost overnight, and so it was that a new generation of medical students came to know ' Uncle George," his clear exposition of the basic principles of surgery, and his leisured operative skill On going to live in Oxford he was made a member of Christ Church senior common-room and he received the degree of M.A. by decree in 1940 He found as great a pleasure in the conversation of the canons and students as they found in him, the atmosphere stimulated his studies into the history of science, and it was at this time that he wrote his essays on the *Early Medical Schools of Greece and Rome* and began work on his unfinished biographical dictionary of ancient Greek physicians

Buzzard soon realised that he had brought to Oxford not only an excellent teacher of surgery but also a man of vision and ideas about hospital coördination Gask became a member of the medical advisory council of the Nuffield Provincial Hospitals Trust and chairman of the medical advisory committee of the Berks, Bucks, and Oxon Regional Hospitals Council. He spurred his committee to action, to collect information, and, in the light of the facts, to plan for the future. Soon memoranda appeared—which were not only of value for the local services but served as models for other centres—on a cancer service, which estimated for the first time the incidence of cancer in terms of the living population and so showed the needs for beds and special equipment, on a comprehensive maternity service, and on child health services Again it was natural that Gask should take part in the hospital surveys initiated by the trust and the Ministry, for as a regional adviser in surgery to the Ministry he had gained an intimate knowledge of the hospitals of his area When the wounded, evacuated from Dunkirk, came to the Oxford hospitals, he was ready with help and advice, and he played a big part in the later plans when air transport was used for bringing casualties from Northern France to Wiltshire

Gask renewed one of his earlier interests by his share in the establishment of the Trust's bureau of health and sickness records at Oxford, and, when the National Health Service came into being he, as chairman of the medical advisory committee of the Oxford regional board, persuaded the officers of the board of their need for accurate statistical information which the bureau could provide.

'It was impossible' writes A. H. T R S, to expect a man even of Gask's stamina, to continue all his activities untrammelled and as his health began to interfere with his enthusiasm, he had, unwillingly but with a good grace, to give up things, first it was his teaching then the chairmanship of some of his committees then the chairmanship of the medical advisory committee, and lastly the chairmanship of the bureau committee But enforced retirement from active membership of a committee did not mean loss of interest, and letters would arrive starting What are you going to do about this ' or Isn't it time so and so was finished ' and there were delightful afternoons at Hambledon in the garden or looking over the Chilterns when plans would be hatched with the aid of Mrs Gask's scones and quince jelly Some little time before his 75th birthday, Gask's friends felt a fitting present would be the publication of some of his historical essays and friends from all over the world subscribed the secret was well kept, but the presentation of a bound copy of the book was wisely a simple and homely birthday party in his bedroom. His pleasure was great, at the thought and for the book but most of all there was surprise that so many people should wish to join in expressing their admiration and affection for him. His modesty was as fundamental a facet of his character as was his enthusiasm and honesty and as he said in Changing Surgery, which in a way expresses his professional credo Let us remember the story of the race of the torch. They were not always the fastest runners who kept their torch alight

In 1913 Professor Gask married Ada Alexandra, daughter of Lieut.-Colonel Alexander Crombie, C.B I.M.S She survives him with one son, Dr John Gask.

suffer relatively more from coronary disease? "Myocarditis," "myocardial degeneration," and the rest, provide the small change of certification. They do very well in default of anything much to go on. Now these expressions, it seems, are found particularly at the "other end of the scale." Is it not possible that their very presence implies the absence of any striking past manifestations such as those of the coronary ischæmic syndromes, that in fact the people whose deaths they purport to explain, though they may have had coronary atheroma if anyone cared to look for it, did not suffer from coronary disease? It can scarcely be suggested that the Registrar General, or any of his henchmen, would so far desert his proper sphere as to hint that doctors weigh the social standing of their late patients before awarding them appropriate causes of death. Neither can it be valid to maintain that, in 1931, only a consultant could be expected to make an accurate diagnosis of this form of heart disease. In that year a consultant, who probably even then would see in public wards many more patients than he saw in private, would have been likely enough to miss a coronary thrombosis, or to call it angina. The deaths of those relatively few victims who succumbed to it without previous chest pain he might well have found almost as inexplicable as did his general practitioner colleagues. He, too, might have resorted to the myocardial degeneration formula. On the other hand, though for long it remained rare, angina had been described in England by Heberden at the end of the 18th century, and its coronary association recognised by Jenner. Most practitioners would certainly be familiar with it. What, in working-class life, apart perhaps from birth and death, could be more calculated to result in a call to the doctor than an unheralded, frightening, and crippling affliction of the bread winner? If such a call was seldom made the implication is that its occasion seldom arose.

Within their limitations, then—and it can scarcely be maintained that this form of statistics is completely worthless—the Registrar General's figures, together with his enlightened observations, would seem to support my contention that the better educated, and the personally ambitious, suffer coronary disease more than do manual labourers.

From Dr Geiringer (Jan. 13) I gather that I am a victim of sublimated Da Costa's syndrome. But he misunderstands me. The division which exists in England today between two attitudes of mind has nothing to do with moral values. For all I know, or care, industry may be a vice and idleness a virtue. And I offer no theories upon ætiological mechanisms. I merely point a parallel.

University of Bristol I. McD. G. STEWART.

RECENT HISTORY OF CORONARY DISEASE

SIR,—In his article (Jan. 6 and 13) Dr. Morris has brought forward a very interesting fact—that, despite the sevenfold increase in the number of cases of occlusive coronary heart disease, there has been during the same period a substantial decrease in advanced coronary atheroma, as defined by the report of calcified lesions in the arteries.

However, from this we cannot deduce that occlusive heart disease may not be due to atheroma without extensive calcification. By way of illustration may I point out that the coronary vessels tend to be constricted during cardiac systole, thus reducing the flow in them and predisposing to thrombosis. It will be apparent that if the vessels are calcified this advanced condition will tend to keep them patent, thus reducing the possibility of thrombosis. Coronary occlusion can thus still be due to non-calcified atheroma.

Ilford I. GORDON.

Obituary

GEORGE ERNEST GASK

C.M.G., D.S.O., M.A. Oxfd, F.R.C.S., Hon. F.A.C.S.

Professor George Gask, who held the chair of surgery at St. Bartholomew's Hospital from 1919 to 1935 and was director of the first professorial surgical unit of the University of London, died on Jan. 16 at his home at Hambledon at the age of 75.

He was educated at Dulwich College, and after spending some time abroad at Lausanne and Freiburg, he entered Barts in 1893, qualifying five years later. From his first appointment as house-surgeon to John Langton he held a succession of junior posts before his election to the staff in 1907, and for several years he lived at the hospital as warden of the medical college.

When war broke out in 1914 he was established as a consultant in surgery, and his bent for chest surgery was already clear. Whether at a casualty-clearing station in France in the early years, or later as consulting surgeon to the Fourth Army, with the rank of colonel A.M.S., he did much to develop the treatment of thoracic injuries. For his services he was four times mentioned in despatches, was awarded the D.S.O. in 1917, and was appointed C.M.G. in 1919. His work on the chest won him the gold medal of the West London Medico Chirurgical Society.

Gask had early gained a reputation as an accomplished operator, and his gentle methods were in striking contrast to those of many surgeons of his generation who thought speed more important than delicate handling of the tissues. But his interests were never limited to his specialty. As he was later to say, he believed a good hospital should be a "seedplot of wisdom," and his interest in medical education was keen and creative. After the war his personality was one of the factors that led to the establishment of the first professorial surgical unit at Barts, and the success of this experimental unit was his justification. How much it owed to him is explained by J. H.:

> "Gask had a remarkable quiet, easy, and friendly manner with everyone, whether it was a colleague, a visiting surgeon, or a junior dresser, but behind this exterior there was at times great force and persistence in carrying out some project or new piece of work which continued until it was completed. He had the knack of choosing good men and gathering them round him on the professorial unit and then giving them a free rein to develop their special interest and work. And thus the unit became a live concern."

As in all live concerns, the flavour of the unit was spiced by the endearing foibles of its chief. Gask had been a keen mountaineer—he was a former secretary of the Alpine Club—and he remained an enthusiastic walker even in London.

> "It was a familiar sight," J. H. continues, "to see him arriving on foot at Barts at nine o'clock, or before, having walked the whole way from his home in Regent's Park, and ready to start a morning's operating. All who worked at his unit will remember him in his characteristic garb of a bath towel thrown over his shoulders as he walked about the operating theatre between cases. A careful conservative operator, he was always outwardly calm, and if difficulties arose he only became calmer."

Indeed, as someone else once said:

> "A really desperate situation would be the signal for packing off the wound and smoking a mental cigarette. His younger assistants he would instruct never to run or even hurry across the Hospital square. No emergency, he would imply, could justify so hasty an approach. If the surgeon was not calm the patient would suffer, and Gask's considera

Notes and News

MEDICAL EXPENDITURE

HE cost of medical care is somewhat higher in the U S.A. n in Great Britain, relative to consumption expenditures, national income, and to income per head of population is conclusion was reached by Mr Seymour E Harris PH.D, fessor of economics in Harvard University, when he dressed the American Economic Association in Chicago t month. He found that in Great Britain (1950) and , U S.A. (1949) the cost of health services was as lows percentage of total consumption expenditure, itain 4 5 and U S.A 5 0, percentage of personal income itain 3 7 and U.S.A. 4 4 (the figures for medical expenditure - head as percentage of income per head were also 3 7 d 4 4) Professor Harris remarked that under the National alth Service more money had been canalised into medicine By virtue of its taxing power the Government forces the tion to spend more on medicine and less on other con nption goods or possibly on investment ' Taking the ures for 1938 as 100, expenditure on various goods and vices in Britain during 1948 is shown in the following figures gether with the prices of these goods and services

	Expenditure	*Prices*
Tobacco	112	388
Alcoholic drinks	93	288
Durable household goods	79	236
Private motoring	35	180
Domestic services	37	218
Other services	120	154
All	104	182

It is clear, said Professor Harris ' that large rises of prices relatively non-essential areas of consumption have tended reduce consumption of these non-essentials When prices ive risen greatly and consumption has increased or has en maintained remarkably well, the explanation is inelastic nsistent) demand. The rise of prices in these sectors of the onomy stems largely from tax policy For example the crease of consumption for tobacco was 12% of prices 288% it the rise of prices after allowing for the increase of ixes was but 50% From 1938 to 1948 tobacco taxes se from £84 million to £610 million. All of this iggests that the British Government by a conscious tax nd to some extent price policy has tended to discourage ie consumption of tobacco alcohol, durable consumers oods &c., and use part of the receipts to stimulate the outlay n medicine Few will dispute the fact that the diversion f spending from alcohol tobacco, radio &c to medicine rings an improved pattern of spending But many in this ountry will not approve governmental intervention in the eld of consumption."

NTERNATIONAL CONGRESS ON CHEST DISEASES

THE First International Congress on Diseases of the Chest, ponsored by the council on international affairs, American College of Chest Physicians, was held in Rome between ept 17 and 22, and was attended by about a thousand lelegates and their wives At the inaugural session the ollege medal was presented to Sir Alexander Fleming, F.R.S for his discovery of penicillin. Altogether more than hundred scientific papers were presented by physicians rom forty countries including the U.S.S.R Delegates from Great Britain included Sir Harold Boldero Dr A. J Benatt, Dr C K. Cullen, Dr W Griffel Dr W Paton Philip Dr P R Trail and Dr M. Weinberger A European chapter of he college was organised with Dr André Meyer (Paris) as he general secretary The regents of the college in Europe who will serve as the executive council for the chapter are Prof Gustav Maurer (Davos Switzerland), Prof Etienne Bernard (Paris) Prof Lopo de Carvalho (Lisbon) Prof Nicholas Oekonomopoulos (Athens), Prof. Eugenio Morelli (Rome) and Sir Alexander Fleming

EMPIRE RHEUMATISM COUNCIL

THE report by Lord Horder the chairman, presented at the annual meeting of the Empire Rheumatism Council in London last Wednesday declares that this body was active in the new and revolutionary field of research opened up by the discoveries of Dr Philip Hench and his colleagues in the U.S.A. At the Westminster Medical School in work aided by a grant from the council, good progress was being made towards the preparation of 'Cortisone' analogues, and the council was publishing a critical quarterly bibliography of cortisone, A.C T H, and related hormonal substances As to the council s education programme, the postgraduate courses held at the Apothecaries' Hall had again been fully attended Inquiry had been made as to the number of physicians of registrar or senior registrar status who were members of the Royal College of Physicians and had at least two years training in some recognised rheumatic treatment centre, and for whom no consultant posts in this specialty were at present available, in October 1950 there were some 15 such senior registrars

The finance committee reported that in 1949-50 ordinary income amounted to £12,222 and legacies brought in £6240 the total expenditure rose to £10,243

Royal College of Physicians of London

Dr J C Broom will deliver the Milroy lectures on Tuesday and Thursday, Feb 13 and 15 at 5 P.M. at the college, Pall Mall East, S W 1 He is to speak on Leptospirosis

Hunterian Society

The annual dinner will be held at Claridge s, Brook Street London, W 1 on Thursday, Feb 15 Tickets (30s) may be had from Mr A. W Badenoch 110, Harley Street, W 1

The subject for the 1951 gold medal essay is the Treatment of Asthma in General Practice The competition is open to all general practitioners Further details may be had from the honorary secretary, Mr Clement Francis, 75, Wimpole Street, London, W 1

Heberden Society

Sir Henry Cohen has been elected president of this society for 1951

Scottish Health Services Council

Prof. J M. Graham F.R.C.S E, Dr W Nicol Gray, Dr G W Ireland Prof G L Montgomery F.R.F.P.S, and Dr E Neil Reid have been appointed members of the council, Dr A. D Briggs and Dr R C Scott Dow, L.D.S have been reappointed All will hold office until Dec. 31, 1953

British Association of Physical Medicine

The association is to hold a meeting in London on Friday and Saturday April 20 and 21 The programme will include a lecture-demonstration by Dr A. C Boyle on Micro waves and a demonstration on Ultrasonics A visit will be made to the R.A.F rehabilitation centre at Headley Court Epsom. Further particulars may be had from Dr W S Tegner, the hon secretary 45 Lincoln s Inn Fields W C 2

Ophthalmic Services

Meeting in London on Jan 17 the general council of the Association of Optical Practitioners called on the Minister of Health to establish the existing supplementary ophthalmic service on a permanent basis like the medical and dental services A further resolution urged members of the association not to take a post in the hospital eye service unless the hospital authority concerned declared its intention that the refraction of non pathological cases shall be actively discouraged.' Mr L. Evershed Martin chairman of the council, told a press conference that it had been estimated that only 50% of opticians would be used in the hospital scheme The remainder ' would be out of practice with no compensation whatever The optical profession is walking the plank."

The Minister of Health

The Rt Hon. Hilary Adair Marquand D.SC M.P has been appointed Minister of Health in succession to Mr Aneurin Bevan, who becomes Minister of Labour and National Service

Fifty years of age Mr Marquand was educated at Cardiff High School and University College Cardiff, where he graduated in history and economics His appointments in this country have included those of professor of industrial relations at University College Cardiff, lecturer in economics at the University of Birmingham and director of industrial surveys of South Wales He visited the United States as Laura Spelman Rockefeller fellow in social sciences in 1925 and as visiting professor of economics at Wisconsin University in 1938 During the war he became successively an acting principal at the Board of Trade, a deputy controller at the Ministry of Labour and finally labour adviser at the Ministry of Production. Since then he has been secretary for Overseas Trade (1945-47) Paymaster General (1947-48) and Minister of Pensions (1948-51) His writings include *The Dynamics of Industrial Combination* (1931) *Industrial Relations in the U.S.A* (1934) *South Wales Needs a Plan* (1936) and *Organised Labour in Four Continents* (jointly 1939)

SIDNEY PHILIP PHILLIPS

M D Lond , F R C P

To write of Sidney Phillips is almost to write of another age for he qualified in 1877, and when he died on Jan 19 in his 100th year he was the second senior fellow of the Royal College of Physicians For many years he was treasurer of the college, and, sitting in the censors' room overlooking Trafalgar Square, he used to recall that he was one of the volunteers who lined the square in the demonstration of 1887 when John Burns was arrested

Phillips studied medicine at University College Hospital, and after holding the usual house appointments there he became a demonstrator of anatomy in the medical school His early intention was to be a surgeon, but at the examination for the London B S , then distinct from the qualifying M B , he was set to amputate a much shrivelled toe To some words of criticism from the examiner, Phillips retorted that the examiner had better do it himself and walked out So ended his career as a surgeon It was a characteristic attitude and a story which he always enjoyed telling

His attention having been thus directed to medicine, he quickly made a name for himself, particularly as an expert on fevers Another of his stories was how he became a diagnostic expert in smallpox after his fellow house-physician fell a victim "I had at least seen one case" In due course he was elected to the staff of the Lock Hospital for venereal diseases, Paddington-Green Children's Hospital, the London Fever Hospital, and St Mary's Hospital, where together with the post of assistant physician he had charge of the children's department for several years He was elected F R C P in 1891

Later, when he was full physician at St Mary's, all students went to Edmund Owen for instruction in surgery, and as inevitably to Sidney Phillips before taking their final in medicine His teaching was direct, clear, and emphatic, and he used the gruelling method of question and answer His students went to him knowing well that their ignorance would be plainly exposed, but also that they would learn much that would be useful not only for the looming examination but also for their future practice of medicine He held examinerships for the Conjoint Board and the University of London

He was a brevet colonel in the 1914–18 war, when he had already resigned from St Mary's at the age of 65 During that war his keen observation and ready deduction led to the arrest of a notorious German spy In later years he was always pleased to declare he identified the spy by his Blücher boots

When he became treasurer of the college in 1924 he proved himself an efficient and astute financier He kept all accounts himself, writing them out by hand, until failing sight made resignation inevitable in 1938 In his last years he was totally blind, but his mind remained alert

Although he never published a book, he wrote many papers on fevers, gastro intestinal diseases, and disorders of the heart and circulation When acute ulcerative colitis was beginning to be recognised as a clinical entity," F L recalls, "Phillips described a series of patients whom he had attended—including the late F J Poynton then recently qualified Phillips's teaching and writings on syphilis of the heart formed much of the background of Carey Coombs's lecture to the College of Physicians, and when William Pasteur in 1908 gave a Bradshaw lecture before the same college on massive collapse of the lung, Phillips supplied him with notes of several illustrative cases

"An accurate observer and clear thinker, his diagnosis, based on the old methods, seldom went astray Though he never failed to attend a post-mortem of one of his own patients, he had little respect for those he dubbed 'test-tube' physicians, and he did not hesitate to say so Despite his several appointments he found time to visit his wards once a week—in addition to his two teaching rounds—when he would write notes on some of his cases, when the patients were discharged all the notes had to be sent to his house, where they remained, registrars' protests notwithstanding He had his foibles He did not believe in diphtheria antitoxin, holding that it increased the incidence of polyneuritis, and he always operated upon his own empyemas, without resection of ribs, on the coal chest in the children's ward—with great success

"He had a fund of anecdote The stories about him were legion and enjoyed by none more than by himself, whilst his caustic humour did not always escape repercussions to which he was completely immune There must be many of the older generation who remember him as a character not likely to be met with again, not lightly to be crossed but with a wealth of friendliness and good counsel, and many who owe much to his teaching and help"

•

MR C E WEST

E B B writes "Your obituary of Charles Ernest West mentions his fearless speech In fact he was a man of outstanding courage in every way His surgical courage matched his extreme skill If operation was a patient's only hope, West would operate, no matter how slender the hope might be His skill gave great speed when that was the patient's need I have seen him perform a really good radical mastoid on a patient whose breathing had ceased, and open a cerebellar abscess in 13 minutes from start to finish For those who worked for him perhaps his outstanding characteristic was his loyalty to his team West would take the blame for anything that went wrong and he would side with his junior against anyone on earth His outspokenness and a certain mischievous love of debunking the pompous militated against a universal popularity, but those who were responsible to him in their work, and also his patients, loved him After his early retirement his strength and skill were such that he used to work a six-ton cutter round the Cornish coast single handed, rejoicing openly in the risk so that it was only to himself About two years later he tore every muscle off a tend Achillis while playing badminton This reduced hi from sail to what he called water-motoring, but I nev heard him grumble After his second marriage he to up the clarinet and he and his wife used to play duet An invigorating and amusing companion, intensely ale and alive to the end, he was also a most amusu correspondent"

EXTRAPLEURAL PNEUMOTHORAX IN THE TREATMENT OF PULMONARY TUBERCULOSIS*

E. MURSTAD
M.D. Oslo
OPLAND FYLKESSYKEHUS, LILLEHAMMER, NORWAY

THE aim of collapse treatment in pulmonary tuberculosis is to close a cavity. We must therefore try in each case to select the procedure which offers the best chance of closing the cavity completely, without leaving a residual cavity, with the least operative risk and the least mutilation of the patient, and preserving as much as possible of the respiratory function of the lungs.

It has been and is the prevailing opinion that an intrapleural pneumothorax is the method of choice, and that an extrapleural pneumothorax or a thoracoplasty should only be considered after an intrapleural pneumothorax has proved unsuccessful. Perhaps the risk of getting a rigid lung after an intrapleural pneumothorax will change this view and lead us to prefer an extrapleural pneumothorax or a thoracoplasty even in cases where adhesions do not preclude an intrapleural pneumothorax.

Operations on the phrenic nerve are of restricted value; they are indicated only in special cases, and are not discussed here.

There remain two methods, extrapleural pneumothorax and thoracoplasty, to be used in cases where intrapleural pneumothorax has failed or has been deemed objectionable.

The common opinion has been that the induction of an extrapleural pneumothorax is a rather poor and unreliable operation, only to be performed where a thoracoplasty is to be avoided. In our hospital ten years ago, when we began to use extrapleural pneumothorax, we followed this rule. But gradually it became evident that extrapleural pneumothorax has merits of its own, and for the past few years it has been preferred unless there is some special contra-indication.

We have performed this operation in over 700 cases, but the statistical data given here are based only on the 600 operated on up to 1947, which were reinvestigated in 1948 by Dr. Leif Martin. He will publish his findings elsewhere.

TECHNIQUE

General anæsthesia has been used in nearly all the cases. A longitudinal incision, 10 in. long, is made between the midline of the back and the margin of the scapula. The scapula is retracted, and 4 in. of the 5th rib is resected. After incision of the periosteum in the bed of the rib a thin layer of loose connective tissue, the endothoracic fascia, appears in the wound. This is used as a plane of cleavage, and the lung is peeled off from the chest wall, first with a finger and then with a small swab on long forceps. Adhesions are cut with a pair of long scissors. Bleeding points are caught with forceps and coagulated. It is important not to enter the pleura or an adherent superficial cavity. Small cavities in the top of the lung, with dense fibrous adhesions in the extrapleural layer, are dangerous. Cavities a little further down are not so dangerous in this respect even if they are large and superficial (but they may perforate later). The lung is freed to the hilum on the mediastinal side; on the chest-wall side the extension of the stripping depends on the size and location of the cavity; an average extrapleural space has its lower limit at the eighth rib laterally.

In some cases it is possible, by pushing with the gauze swab, to separate the diseased segment from the healthy part of the lung, thereby getting a very selective collapse. This separation is started posteriorly in the interlobar line, and continued in a horizontal direction anteriorly. The diseased segment seems to contract during this manipulation, and at the end of the operation it looks like a firm globe, the size of a small orange, on top of the remaining non-collapsed lung.

The extrapleural space is partially filled with an anticoagulant fluid, 300 ml. of a 1% solution of sodium citrate. This fluid will have to be renewed frequently during the first few days. To spare the patient frequent needling, and to obtain better aspiration, a soft rubber catheter is passed through the 8th intercostal space posteriorly, and laid along the chest wall as far as the lower end of the incision, beneath the muscles (forming a kind of Witzel fistula), to prevent leakage when it is removed.

The entrance to the extrapleural space is closed with two pericostal catgut sutures and a continuous silk suture in the intercostal muscles. A continuous silk suture is also used in two layers in the rhomboid and trapezius muscles. After the skin has been sutured, penicillin 50,000 units is injected through the catheter, which is then closed and put beneath the bandage.

A few hours later the fluid is aspirated and a fresh solution of sodium citrate and penicillin is injected. The frequency of further aspirations depends on the amount of bleeding, as suggested by the patient's sensation of pressure in the chest and by the radiographs. The catheter is removed on the fourth day, and the later aspirations are done by acupuncture. The patients are allowed out of bed the day after the operation.

During the first week there is no danger of the pressure in the extrapleural space getting too low, permitting the lung to re-expand; the hæmorrhage and the secretion of wound fluid will prevent this. But after a week or two great care must be taken with the pressure, and refills must be given every other day for two to four weeks, then twice a week for two to four months, after which the intervals are gradually lengthened until, after a year, refills are made every two to four weeks.

ADVANTAGES

The advantages of an extrapleural pneumothorax are obvious:

(1) The operation does not carry with it any deformity. This is very important. Patients are often more worried about the disfiguration after a thoracoplasty than is commonly supposed. In our hospital we have had as house-surgeons several young men who had recently had pulmonary tuberculosis and had lived as patients in sanatoria, and they have all told me that most patients, men as well as women, worry a great deal about their deformity after a thoracoplasty.

(2) Extrapleural pneumothorax is a one-stage operation.

(3) Above all, it gives a more complete and more selective collapse than any other procedure.

The ideal procedure would free the diseased segment of the lung only, permitting it to retract completely, while the rest of the lung remained undisturbed in contact with the chest wall. An extrapleural pneumothorax gives a nearly ideal collapse, more selective than an intrapleural, especially when it is possible to do an intersegmental stripping. (In two cases we have established an extrapleural pneumothorax over the lower lobe, separating it from the upper lobe, which has remained in contact with the thoracic wall.)

Modern thoracoplasty, in which long lengths of the ribs over the diseased part of the lung only are resected, gives a rather selective collapse, but the collapse after an extrapleural pneumothorax is still better. When a pneumolysis is added to a thoracoplasty, the collapse is, to begin with, nearly ideal, just as in an extrapleural pneumothorax. But later the collapsed lung will partially re-expand, to fill the empty space which is created when the air and the wound fluid are gradually absorbed. One can observe this when doing the second stage of a thoracoplasty, and one can follow the re-expansion by radiography.

This re-expansion may perhaps be prevented by filling the space with air or oil for a few weeks until the

* A lecture read to the Department of Thoracic Surgery, Royal Victoria Infirmary, Newcastle upon Tyne, on Oct. 5, 1949.

Mycological Reference Laboratory

Dr Jacqueline Walker has been appointed acting director of the laboratory on the resignation of Dr R W Riddell Specimens for examination for pathogenic fungi should be addressed to her at the laboratory, London School of Hygiene and Tropical Medicine, London, W C 1

Tuberculosis-free Dairy Cattle

Addressing a conference reported in the *Farmer and Stockbreeder* for Jan 16, Mr Ben Hinds, chairman of the Milk Marketing Board, said that 36% of the milk sold last month in England and Wales was from tuberculin tested cows In the three counties of West Wales (Carmarthen, Cardigan, and Pembroke) the proportion was 77% This area has been selected as the first area in Britain for free tuberculin testing under the attested herds scheme

Medical Artists' Association of Great Britain

Applications for membership of this association will be considered at a meeting of the examining subcommittee on April 6 Forms of application and full details may be obtained from the hon assistant secretary, Miss Audrey J Arnott, A R C A, The Rotunda, Radcliffe Infirmary, Oxford Work for the examination must reach Miss Arnott, c/o Dr Tompsett, at the Royal College of Surgeons, Lincoln's Inn Fields, London, W C 2, by April 4

Statistical Research

The World Health Organisation has set up, from Jan 1, a centre for statistical research on problems arising in the use of the International Statistical Classification of Diseases, Injuries, and Causes of Death, and has appointed Dr Percy Stocks, until recently chief medical statistician at the General Register Office, to direct its work. The centre is at present situated at the General Register Office, which is providing appropriate material from its records Dr Stocks will continue for the present to be available to the department in a consultant capacity

Use of Preservatives in Food

The Food Standards Committee of the Ministry of Food has set up a subcommittee to consider the use in foods of preservatives, colouring matters, dyestuffs, and allied substances such as anti oxidants, anti staling agents, anti mould agents, stabilising agents, and emulsifying agents The ten members include the following doctors Prof E C Dodds, F R S (chairman), Dr N R Beattie, Prof S J Cowell, and Dr J M Johnston. The subcommittee may be addressed at the Ministry of Food, Food Standards and Labelling Division, 47, Portman Square, London, W 1

Hospital Administrative Staff College

Mr R A Mickelwright, F H A, and Mr A C Stuart Clark, M A, have been appointed by King Edward's Hospital Fund for London as whole time members of the tutorial staff of the college, at nos 2 and 14, Palace Court, W 2 Mr Mickelwright, who will act as senior tutor and director of studies, is resigning his appointment as secretary to the South West Middlesex Hospital Management Committee Mr Stuart Clark, who will act as senior tutor and registrar, was formerly headmaster of Brighton College The principal of the college is Mr P H Constable, M.A, F H A, house governor of St George's Hospital, who will act in a part-time capacity The first courses will begin at the college in April

Lady Tata Memorial Trust

The trustees of this fund invite applications for grants and scholarships for research on diseases of the blood, with special reference to leukæmia, in the academic year beginning on Oct 1, 1951 Grants are made for research expenses or to provide scientific or technical assistants for senior workers Scholarships are awarded as personal remuneration, and are intended chiefly for junior investigators working under suitable direction, their normal value has been £400 per annum for whole time research, with proportionate adjustment for work on a part time basis The grants and scholarships are open to workers of any nationality, and in any country in which it will be possible to make payments in the coming academic year Applications must be submitted before March 31, and the awards will be announced by the trustees in June Forms of application may be obtained from the secretary of the scientific advisory committee c/o Medical Research Council, 38, Old Queen Street, London, S W 1

Renal Association

At a meeting of the association on Wednesday, Jan. 31, a 4 30 P M, at the Ciba Foundation, 41, Portland Place, Lond W 1, Prof E C Amoroso will speak on the Fœtal Kidn Prof E B Verney, F R.S, on the Neurohypophysis and t Kidney, and Dr Dent on Tubular Function

Memorial to C J Bond

On Jan 10 Prof G Grey Turner unveiled a memorial tabl to C J Bond in the Leicester Royal Infirmary where he ha served as an active surgeon for 27 years and as a consult surgeon until his death in 1939 at 83 The same even Professor Grey Turner delivered the first Bond memori lecture, before the Leicester Medical Society

Society for Endocrinology

This society will hold a symposium on Endocrinologica Aspects of Fertility at the house of the Zoological Soci Regent's Park, London, N W 8, on Friday, Feb 16, at 11 A Those who wish to attend should write to Prof C H Gr department of chemical pathology, King's College Hospital London, S E 5, not later than Feb 10

PHILLIPS —On Jan 19 in London Sidney Philip Phillips M.D Lond F R C.P aged 90

RAWLINSON —On Jan 14 at West Kirby, Cheshire James Herbert Rawlinson M D Lpool F R C.S and the occupation Today postoperative infection of the extrapleural space is very rare

The evils and complications commonly adduced as objections to an extrapleural pneumothorax—the difficulty of maintaining the extrapleural space, the risk of hæmorrhage, and the risk of pyogenic infection—should not be overemphasised In our view the main disadvantages are the late complications—the tuberculous empyemas and, above all, the bronchial fistulæ

It is a matter of judgment which cases should be counted as empyemas Many patients have a scanty cloudy fluid in the extrapleural space, often growing tubercle bacilli on culture The fluid may be present for a long time, it disappears either spontaneously or after a few aspirations The general health of the patient is not impaired These cases I have not counted as empyemas, nor the cases in which the fluid has been more purulent but has not tended to increase Such cases excluded, there have been 73 cases (12%) of tuberculous empyema Of these 73 patients 12 died, 10 of them of bronchial or œsophageal fistula

The most serious complication, and the strongest objection to the extensive use of extrapleural pneumothorax, is the bronchial fistula In our series there were 28 cases (4 7%) of bronchial fistula and 3 cases of œsophageal fistula

What is the ætiology of the bronchial fistula ? We have done a necropsy in 6 cases, and 4 showed an identical picture the lateral wall of the tuberculous cavity was almost entirely destroyed, the rest of the cavity forming a shallow crater, into the floor of which opened a bronchial branch Of these 4 patients, 3 had got their fistulæ within two months after the operation In 13 of our 28 cases the bronchial fistula had developed within four months after the operation, so probably the pathogenesis of the fistula in most of these early cases is the same—necrosis of the wall of a superficial cavity

In 15 cases the bronchial fistula developed several months after the operation, and in 11 of them the patients had had tuberculous empyema for weeks and months before showing signs of a bronchial fistula—expectoration of purulent fluid and impossibility of raising the pressure in the extrapleural space by refills (It may be impossible in any given case to tell which is primary, the empyema or the fistula)

If large superficial cavities and long standing empyemas are important ætiological factors in the development of bronchial fistulæ, extrapleural pneumothorax should be avoided in cases with large superficial cavities, though it may be right to deliberately run the risk of a bronchial fistula if there are weighty indications for preferring an extrapleural pneumothorax to a thoracoplasty—e g, bilateral tuberculosis with low vital capacity and poor general condition And care must be taken to evacuate an empyema often enough to prevent it from perforating into the lung and yet not too often

RESULTS

To assess the results it is absolutely necessary to group the cases, though strong objections may be raised to any system of grouping

The operative mortality and the chances of closing the cavity depend to a large extent on the following factors

1 The size and the position of the cavity The larger the cavity the greater is the risk of postoperative spread

2 *Respiratory function* The best way of assessing the respiratory function is to observe the patient in everyday life But to provide an objective scale we have used the vital capacity (we have not computed the percentage of normal taking the patient s weight and height into consideration)

3 The resistance of the patient the phase of the disease

We have adopted the following classification for unilateral operations

Group	Maximum diameter of cavity (cm)	Cavity not below	Minimum vital capacity (c cm)	Phase
I	4	5th rib	2500	Good
II	5	5th rib if there is an intrapleural pneumo thorax on the other side	1300	Average
III				

Patients who fail to meet one or more of the criteria for a group are placed in the next lower group

Cases in which operation on both sides was either performed or planned are placed in group IV

As operative deaths we have counted those which seemed to be a consequence of a complication (usually pulmonary) with a plausible causal connection with the operation, regardless of the time elapsed between the operation and the death, and regardless of the patient's having left the hospital or not

Group I

In group I (fig 2) there were 107 patients, of whom 2 died (both from pulmonary embolism), 2 had pulmonary complications, and 2 infection of the extrapleural space Of the 105 surviving patients, 101 (96%) had a negative sputum and 4% a positive sputum

Fig 3 shows that of the 101 patients with negative sputum 89 (88%) had remained negative and 12 had become positive in one to eight years Only 1 of the recurrences was on the operated side

Group II

In group II (fig 2) there were 166 patients, of whom 11 (6 6%) died In 6 cases death was due to pulmonary embolism (Most of the embolisms occurred in infected cases During the period when there were many infections of the extrapleural space, we often saw thrombosis in the arm and always on the operated side During the later years, when there were no infections, there was no thrombosis and no embolism Is this a coincidence, or has there been a causal connection between infections of the extrapleural space and thrombo embolism ?) 4 8% had pulmonary complications and 4 2% infection Of the 155 surviving patients 127 (82%) had a negative sputum

Fig 3 shows that after one to eight years 112 (88%) of the 127 patients remained negative, and 12% had become positive Most of the recurrences were in the non operated lung

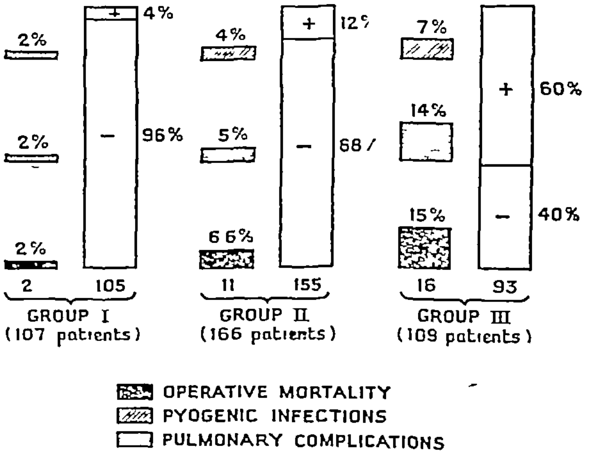

Fig 2—Immediate results of extrapleural pneumothorax White columns show sputum findings in each group

ribs covering the collapsed lung have regenerated This procedure to some extent relinquishes one of the essential advantages of thoracoplasty—i e, absence of a dead space with its inherent risk of infection and bronchial fistula But perhaps the additional layer covering the collapsed lung may give some protection against the development of a bronchial fistula

DISADVANTAGES

An extrapleural pneumothorax gives a reversible collapse This is an advantage in cases requiring only a temporary collapse, but a drawback when a permanent collapse is desired But I cannot see why an extrapleural pneumothorax should not be maintained permanently After a year the intervals between refills can be lengthened up to four weeks, and a visit to the doctor every four weeks is not a very great burden for the patient, provided he does not live too far from a hospital or a physician who can do the refills properly An extrapleural space always carries the risk of infection leading to tuberculous empyema or bronchial fistula, but experience has shown that these complications decrease in incidence when some months have elapsed after the operation Moreover, it is not easy to tell beforehand in any given case whether a permanent collapse will be required or not

It is commonly said that a cavity which has been treated by intrapleural pneumothorax and has reopened has proved that it demands a permanent collapse, and therefore should not be treated by extrapleural pneumothorax But in many cases it is doubtful whether the intrapleural pneumothorax really has offered the diseased segment of the lung the opportunity of a complete collapse In doing an open intrapleural pneumolysis I have often seen that the adhesions are much stronger than would be expected from the findings on thoracoscopy and radiography

A bronchial stenosis is considered a contra indication to all forms of temporary collapse, and therefore to an extrapleural pneumothorax The stenosis is supposed to prevent the lung from re expanding when the refills are discontinued, and, if the lung does re expand, there will be a risk of bronchiectasis This question needs further investigation It is hard to know how much of this belief is based on facts Moreover, streptomycin may possibly change the outlook

It may be impossible to establish an extrapleural pneumothorax, because of adhesions This happened in 21 (3%) of our cases One cannot tell beforehand in any given case whether the operation will be possible or not, the only warning sign of any value is the appearance of very narrow intercostal spaces on the radiographs

It is important not to force the operation, but to abandon the pneumolysis and do a thoracoplasty if the separation of adhesions is too hazardous, perforating a cavity is a very tragic event We have perforated a cavity in 6 cases (1%) I think some of these accidents ought to have been avoided, but I do not think one can completely avoid this calamity without being too cautious, abandoning too many pneumolyses

A further contention is that the maintenance of extrapleural pneumothorax is often difficult, and that it is often impossible to prevent the extrapleural space from shrinking and allowing the lung to re expand before the cavity is healed

The extrapleural and the intrapleural spaces are very different The extrapleural space is a wound space, lined with vascular connective tissue If the lung is allowed to expand, even to a small extent, adhesions are rapidly formed in the sinus (x, in fig 1) between the lung and the chest wall, and what is lost in this way is lost for ever, it cannot be regained later by refills Therefore one must be very careful to keep a sufficient pressure in the extrapleural space, preventing the lung from coming into contact with the chest wall in the sinus, even for a short time It is not necessary to have a very high pressure, but to avoid very frequent refills it is practical, and harmless, to raise the pressure to 30–40 cm of water

After two or three months the wall of the extrapleural space is no longer a wound surface In re operations and at necropsies at such a time the extrapleural space is found to be lined by a smooth, shining white membrane not unlike pleura The danger of rapid formation of adhesions is then much less, and the intervals between the refills can be lengthened

If there are blood clots in the recess of the extrapleural space these may become organised and cause shrinkage even if the air pressure is kept at the proper height To prevent this we have filled the extrapleural space partially with an anticoagulant fluid We have not succeeded in completely preventing the clotting in all cases, but I believe this device has been of considerable help The prevention of clotting and the more complete evacuation of blood may also be of importance in the prevention and treatment of infections of the extrapleural space

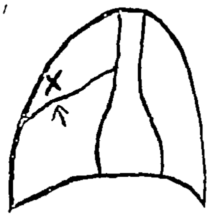

Fig 1

With due care it is nearly always possible to maintain an extrapleural space as long as one wishes In 6 (1%) of our cases the lung re expanded soon after the operation, these cases were all among our early ones

Tearing of the pleura, causing an intrapleural pneumothorax, occurred in 24 cases (4%) This accident may to some extent, but not completely, be avoided by careful technique We have succeeded in closing the ruptured pleura airtight in only 1 case In most cases we have removed the diaphragm between the extrapleural and the accidental intrapleural spaces, but these combined spaces do not do very well, there being often much reaction and much trouble in the after treatment Perhaps the best thing to do is to inflate the lung, close the wound, and operate again after some weeks, when adhesions have formed

Hæmorrhage is often alleged to be a grave objection to the extrapleural pneumothorax The blood loss during the operation is in most cases 200–300 ml Bleeding uncontrollable by the usual means has occurred in 7 cases (1%) In 2 of these we did a thoracoplasty to get at the bleeding vessel, and in the remaining 5 we put in a pack, closed the wound without drainage, and re operated two days later

A far more serious problem is postoperative bleeding—oozing from the large wound surface of the extrapleural space We have tried to calculate the postoperative blood loss by estimating the amount of hæmoglobin in the aspirated fluid A third of the patients lost more than 2 pints, and a tenth lost 4 pints or more The hæmorrhage has in many cases been rather alarming, in 1 case 22 transfusions were given 1 patient died despite numerous transfusions (It is impossible to tell what part hæmorrhage has played in the mortalities counted as due to infection or spread of tuberculosis in the lungs)

Early postoperative pyogenic non tuberculous infection of the extrapleural space developed in 29 cases (5%), and 7 of these patients died This is a regrettably high incidence of postoperative infection During the last two years there has been no infection in 162 cases This improvement may be due to penicillin, but it must be borne in mind that there was a remarkably high incidence of pyogenic infections in our population during the war anus to the splenic flexure, and absence of ganglion cells was noted in both cases In two girls who died at 3 weeks and 4 years no necropsy was done but a narrow segment was demonstrated at laparotomy in the infant and by barium enema in the older child extending to the splenic flexure in the infant and to the pelvirectal junction in her sister In one other child (sex not given), who died at 3 days with symptoms of intestinal obstruction, barium enema suggested an abnormal segment probably involving the entire colon, organic obstruction was excluded at necropsy We consider these last 3 children clinically proved cases of Hirschsprung's disease The other 6 siblings (1 boy and 5 whose sex was not mentioned) were unaffected The father aged 37 was reported to be well but constipated since birth

Buttersack (1927) described a family in which a man, his son, a niece and a nephew were probably affected with Hirschsprung's disease The father aged 38 had symptoms of chronic intestinal obstruction from early childhood at 35 his descending and sigmoid colons were resected and were found to be enormously dilated and hypertrophied though there was no obstruction on the distal side His son died at 5 weeks with intestinal obstruction and necropsy showed hypertrophied and dilated colon and sigmoid but no stenosis distally A niece, aged 4 years at the time of the report had symptoms of intestinal obstruction since birth. A nephew died of intestinal obstruction at 11 days, there was no necropsy

Popper (1920) reported on a pair of female twins One had passed no meconium and died at 4 days from intestinal obstruction there was no necropsy The other twin was treated with repeated enemas for retention of meconium and was reported alive at 28 weeks though with a distended abdomen and visible peristalsis the barium enema X ray film published shows a typical narrow segment of average length No evidence is given whether these twins were monozygous or dizygous We consider that the first twin was probably a case of Hirschsprung's disease and we accept the radiological evidence in the other as proof of the diagnosis

1—Index case 31 and his affected twin brothers.

PRESENT INVESTIGATION

Since there are now definite pathological criteria for the diagnosis of Hirschsprung's disease, it seemed worth while to investigate the incidence of the disease in the families of a consecutive series of histologically established cases At the Hospital for Sick Children 40 cases were available for this study and by chance the children were all unrelated, 37 of the 40 were boys One was an adopted child The parents of 3 others had emigrated, but in one of these cases the grandparents provided a family history The series, therefore, includes 37 index cases of Hirschsprung's disease in which the diagnosis was established by histological examination of surgical or necropsy specimens of bowel.

The parents were interviewed and asked about their own health and that of their other children, their brothers and sisters, and their nephews and nieces With the exception of 2 adult sisters of one index case and 5 adult sisters of another, all brothers and sisters of the index cases were examined clinically for abdominal distension and by straight radiography of the abdomen for colonic dilatation Barium enemas were given in doubtful cases

Findings in Siblings

In the following 4 siblings there was radiological proof of Hirschsprung's disease None of these was found as a result of our investigation—2 were known to us before we began this work, and 2 twin brothers of one index case were brought to the hospital by their mother during our investigation but before we had written to her

Sibling Case I—Elder brother of index case 29 (fig 2), admitted under Mr Denis Browne Two sisters alive and well Passed meconium on the third day Constipated since birth, abdominal distension noted from age of 3 weeks Vomited occasionally Motions small and thin. Required regular aperients and weekly or fortnightly bowel washouts. Barium enema at 21 months showed greatly distended sigmoid and descending colon and narrow rectum, typical of Hirschsprung's disease Examination at this hospital three weeks before death showed very tense large and hard abdomen with palpable fæcal masses Died at home at age of 2 years 4 months No necropsy

Sibling Case II—Younger brother age 14½ yr., of index case 26 (fig 2) admitted under Mr T Twistington Higgins The firstborn of this family, a boy had died at the age of 9 days from "stomach trouble" and is discussed below The patient had been examined at the age of 13 by a mass radiography unit when an enormously distended colon was found. The family doctor, knowing the condition of the older brother, referred the patient to this hospital at the age of 14. His complaints were minimal. He needed liquid paraffin since starting school There was occasional abdominal distension with flatus at night He had a moderately enlarged abdomen, displaying enormous peristaltic waves and an empty rectum, and a barium enema revealed a typical narrow distal segment of intermediate length. He is being treated conservatively

Sibling Cases III and IV—Younger twin brothers of index case 31 (figs 1 and 2), admitted under Mr Charles Donald age 3½ yr An older sister is normal. Their mother brought the twins to the hospital because she thought they were also affected

One twin weighed 7 lb 3 oz. at birth. He was well until the end of the first year of life but then he gradually became increasingly constipated requiring daily laxatives His weight gain was normal His abdomen was less enlarged than his twin brother's and he was slightly the taller of the two Barium enema revealed a typical short narrow segment affecting the rectum.

The other twin weighed 6 lb at birth He began to vomit every feed at 7 weeks and was then an inpatient at a local hospital for six weeks Constipation began at 1 year and became gradually more obstinate necessitating laxatives every day His abdomen had been protuberant since the age of 1 year His weight gain was normal. He was pot-bellied with a tympanitic abdomen in which fæcal masses

Group III

In group III (fig 2) there were 109 cases, many of them very poor cases, and the mortality was high (15%) Most of the deaths were due to spread of tuberculosis The frequency of spreads and of infection was high, being 14% and 7% respectively Of the surviving 93 patients 38 (40%) had a negative sputum

Fig 3 shows that after one to eight years 29 (78%) of the 38 patients had remained negative There were 7 recurrences, 2 in the operated and 5 in the non operated lung In 2 cases there was only a single positive culture during a cold, between several negative cultures

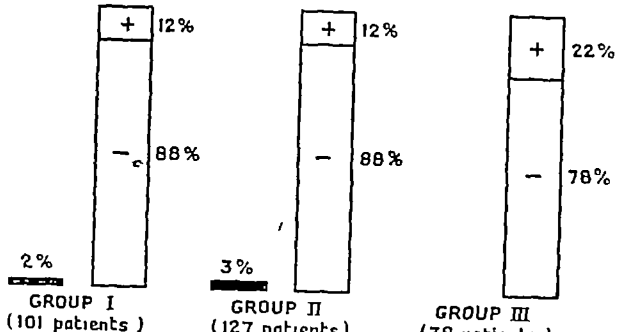

Fig 3—Follow up 1–8 years later of patients who had negative sputum immediately after operation

Group IV

Group IV was very heterogeneous, comprising good and poor cases, and cases treated by combinations of thoracoplasty and extrapleural pneumothorax In 139 cases extrapleural pneumothorax was planned on both sides In 82 of them the operation on the second side was abandoned, leaving 57 cases of bilateral extrapleural pneumothorax The operative mortality was 10% (13 patients died after the first stage, and only 1 after the second stage) Of the 57 patients who underwent the bilateral operation, in 41 (72%) the sputum became negative After one to eight years 1 of these 41 patients had died of pulmonary tuberculosis, 1 of renal tuberculosis, and 1 of rheumatic carditis The surviving 38 patients were free from clinical symptoms, and their radiograms showed no recurrence, but 5 of them had one positive culture during a cold, among numerous negative cultures 35 were able to work It is often astonishing to see how well patients with rather large extrapleural spaces on both sides are doing If their diaphragm is not rigid, and if they have learnt to breathe with their abdomen, they are not much troubled by shortness of breath

CONCLUSIONS

In summing up, I shall not try to draw strict and clear-cut conclusions about the value of, and the indications for, extrapleural pneumothorax I believe, however, that the advantages of this procedure have been underestimated, and the disadvantages exaggerated.

The most serious disadvantage is the risk of bronchial fistula

We must learn to know more about what happens when the refills are discontinued and the lung is allowed to expand The cases we have followed for periods of one to eight years have done well, but what will happen to them in another three or four years remains to be seen

Regardless of what will then be found, we can now say that in bilateral cases, and in poor cases, extrapleural pneumothorax is very valuable and in some desperate cases enables us to do something for patients who otherwise would be left untreated.

THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET, LONDON

THIS paper is based on 40 consecutive cases of histologically confirmed Hirschsprung's disease, and our purpose is to record (1) a genetic study of the disease in the families of 37 of these children, (2) a follow up account of the 37 cases treated by rectosigmoidectomy, and (3) our views on the pathology, especially in relation to the length of the abnormal bowel segment Lastly (4), we shall describe an example of a hitherto unreported condition which may be a variant of Hirschsprung's disease

Bodian et al (1949, 1950) have classified megacolon without organic obstruction into two principal groups Hirschsprung's disease proper and idiopathic megacolon.

The second group is much the commoner and the megacolon results from chronic constipation, which is probably acquired some time after birth Retention of fæcal material leads to passive dilatation of the colon and rectum and to shortening and flattening of the anal canal The radiological diagnosis from Hirschsprung's disease is made by demonstrating dilatation to the anus. The condition is benign and susceptible to persistent treatment with bowel washouts

Hirschsprung's disease proper is a congenital malformation, only microscopically demonstrable, affecting a variable length of terminal bowel The pathology is an agenesis of intramural ganglion cells and a dysplasia of autonomic nerve bundles Its functional manifestation is lack of coordinated peristalsis in the affected segment, leading secondarily to an active type of megacolon in the bowel proximal to this The demonstration by barium enema of undilated or narrow bowel distal to the megacolon is diagnostic Resection of the inert distal bowel by rectosigmoidectomy is now considered the rational treatment of Hirschsprung's disease

A Genetic Study of Hirschsprung's Disease

The few published reports on the familial incidence of Hirschsprung's disease refer only to isolated families, and most of them are not based on adequate diagnostic (radiological or pathological) criteria We shall discuss only four of these reports—two in which the diagnosis was confirmed histologically (Dalla Valle 1920, 1924, Zuelzer and Wilson 1948), one in which a condition that was probably Hirschsprung's disease affected more than one generation (Buttersack 1927), and one in which Hirschsprung's disease was probably present in a pair of twins (Popper 1920)

PREVIOUS PUBLICATIONS

Dalla Valle (1920, 1924) reported on 2 brothers who died at 10 months and 16 months with megacolon Histological examination in both cases revealed absence of ganglion cells from Auerbach's plexus in the sigmoid colon, which was of normal calibre Normal ganglia were found in the dilated colon These children had two normal brothers and two brothers who died at 6 and 14 days with symptoms of intestinal obstruction and probably had Hirschsprung's disease

Zuelzer and Wilson (1948) gave details of 11 of the 12 children in a remarkable family One boy and one girl died at 14 and 15 days with intestinal obstruction, at necropsy long narrow segments of bowel were found extending from the fig 6) Proximal to this again, normal intramural plexuses were found (fig 7) It is not possible, from the macroscopic appearances, to predict exactly the sites of transition from normal to transitional and to aganglionic segments As a rule the surgeons at this hospital have resected, in addition to the terminal undilated segment, rather more than the distal half of the funnel shaped zone proximal to it Our follow up shows that this is adequate

We have not yet observed the rare variant of zonal absence of ganglion cells with normal ganglia both proximal and distal to the zone, but 3 examples of this have been reported by Perrot and Danon (1935), Tiffin et al (1940), and Swenson et al (1949)

One of our infants, who died at the age of 17 days, had a pathological segment of bowel extending from the anal margin to the splenic flexure The proximal limit of the aganglionic zone in the other 39 cases was never above the junction of sigmoid and descending colon, and was usually well below this, though it varied from case to case

We have surveyed all the published cases (including our own) in which observations were made on the abnormal segment and some indication was given of its length The total number was 160 In 14 of these there were very long segments to the splenic flexure in 9, hepatic flexure in 1, ileocæcal valve in 1, and distal ileum in 2 Twelve of these children died at the age of 1 month or less and one at the age of 5 months One newborn baby with an affected segment reaching to the splenic flexure was twice operated on by Swenson (1950), who removed the abnormal bowel, the infant has survived The remaining 146 children had segments not extending beyond the rectum and sigmoid, and 6 of these died in the neonatal period

If only histologically confirmed cases are considered, the total is 90, of which 8 had very long segments (splenic flexure 5, hepatic flexure 1, distal ileum 2), 82 had "rectosigmoid" segments, and only 1 died in the neonatal period

The number of reported neonatal deaths from Hirschsprung's disease is only about 10–12% of the total children affected, most of these fatal cases were of the long segment variety

Several interesting points arise from this survey

(1) The "long segment" variety of Hirschsprung's disease comprises somewhat less than 10% of all cases It is probably incompatible with life unless treated, and the affected children usually die in the neonatal period

(2) The "short-segment" and "intermediate segment" varieties form the vast bulk of all cases (at least 90%) Relatively few of these die in the neonatal period The pathological segment is in the rectum and often also involves part or all of the sigmoid The term rectosigmoidectomy is a highly appropriate description of the operation needed in this group

(3) The histological appearances in all these cases are identical

(4) The occurrence of long and short pathological segments in different siblings of one family (Zuelzer and Wilson 1948) suggests that they are genetically the same

INTERPRETATION OF PATHOLOGICAL FINDINGS

It has been suggested that the proximal colon receives its parasympathetic nerve supply from the vagus, while the distal end of the colon is supplied by the parasympathetic pelvic nerves, and that Auerbach's plexuses contain ganglion cells of the parasympathetic supply to the bowel

Swenson (1950), considering Hirschsprung's disease to be a failure of development of Auerbach's plexuses in rectum and rectosigmoid, suggests that failure of the pelvic parasympathetic nerve supply to develop may be the explanation of the location of the aganglionic lesion This theory is hardly compatible with the great variability in length of the aganglionic segment

We suggest that the primary pathology of Hirschsprung's disease is an agenesis, in a distal part of the gut of variable length, of the ganglion cells which form Auerbach's and Meissner's plexuses, and that this change is not conditioned by any failure of development of the extrinsic nerve supply of the intestine Embryological development generally begins at the cranial extremity and progresses caudally If this applies to the intramural ganglion cells, a genetically determined disturbance of development with variable time of onset would explain long, intermediate, and short aganglionic desirable (1) for other workers to make similar investigations and supply additional data on familial incidence and on twins, and (2) to follow our successfully treated patients through their marital life and study their offspring

As this paper was going to press, a histologically established case of Hirschsprung's disease in a man of 54 was reported by Rosin et al (1950) from the Mayo Clinic The man has three normal children but their sex is not stated

Genetic Prognosis

Provisionally, we suggest that parents who have one child with Hirschsprung's disease should be told that the chances of the disorder occurring in subsequent female children are small, and in subsequent male children about 1 in 5 From a series of this size one cannot determine whether a calculated average chance will apply equally to any particular family It is possible that in families where two children have been affected the chances of the disease occurring in subsequent male children are considerably higher, and in those with one affected child they are correspondingly lower, resulting in the same average figure as if the series was homogeneous

Follow-up of Cases after Rectosigmoidectomy

The first 12 and the next 14 cases treated by rectosigmoidectomy at this hospital have already been reported (Bodian et al 1949, 1950) During 1950 a further 11 children have been operated on, and we can now summarise the follow up results in all 37 cases

There have been 3 deaths in the series 2 under anæsthesia and 1 from peritonitis The follow up period is calculated from the final closure of the colostomy after rectosigmoidectomy, and 2 of the cases are too recent to be included The remaining 32 children were divided into three groups 12 followed for two years or longer, 11 followed for a year to a year and eleven months, and 9 followed for six to eleven months All these children have recently been examined, and their data are summarised in fig 4

The 32 children are all in excellent general condition All but one pass regular and spontaneous motions, roughly half without laxatives, the remainder are given aperients by their mothers Only 3 complain of occasional abdominal distension Some pass flatus at night but experience no difficulty Some soil their pants occasionally, but there is a tendency to grow out of this habit and to acquire complete sensory and motor control with age

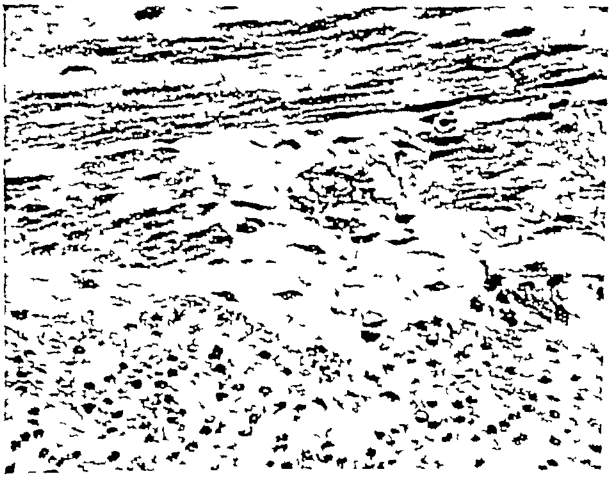

Fig 6—Intramural plexus in transitional zone (× 300)

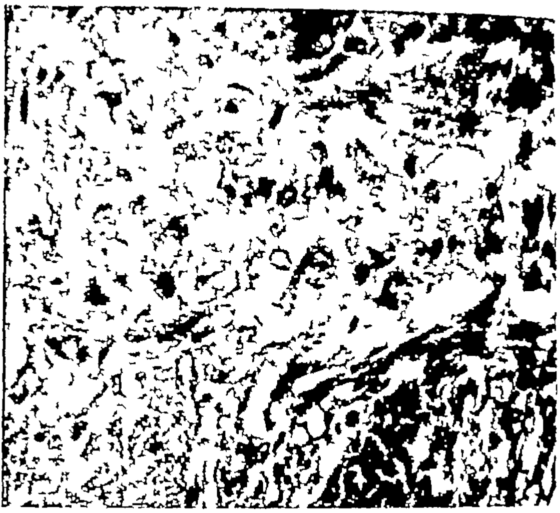

Fig 7—Intramural plexus in dilated segment with normal ganglion cells (× 280)

The weights of the children have been rather informative We have not considered their weights before surgical treatment because fæcal accumulations tend to vitiate the figures We have merely compared the weights at the time of closure of the colostomy with present weights and related these figures to norms for the age

Of the first 12 children only 1 is still below average The remainder are now of average weight or well above it, 6 of these had previously been underweight but have caught up

Of the second group of 11 cases, 3 underweight children are now of average weight, 1 is catching up, and 1 is still well below average

The last group, of 9 children, were all of average weight at the time of closure of the colostomy and have maintained or exceeded the normal rate of weight gain

Three children had anastomotic anal strictures which were treated by dilatation with improvement, their general progress has not been affected adversely One child had a bladder palsy which recovered completely after six months' treatment One has relapsed owing to a residual short narrow segment, he requires daily enemas but has otherwise made good progress

None of the children were recently given barium enemas In our last report, however, we demonstrated a considerable regression in the size of the dilated colon which had been anastomosed to the anal canal

Pathology

THE LENGTH OF SEGMENT INVOLVED

Histological examination in all our 40 cases of Hirschsprung's disease uniformly revealed the characteristic pathological findings previously reported (Bodian et al 1949) Two of the children died in the neonatal period, one died after subtotal colectomy, and of the 37 cases treated by rectosigmoidectomy, in which the resected bowel segments were submitted for investigation, 3 died and necropsies were performed on them

No ganglion cells were found in the undilated or narrow distal segment of bowel and in a few centimetres of adjoining hypertrophied dilated intestine Abnormal non medullated nerve trunks were present at the customary sites of the intramural ganglia, they were largest in the rectum and anal canal (fig 5) Proximal to the aganglionic segment there was a short transitional zone of scanty small abnormal ganglia to point of maximum distension 65 cm from duodenojejunal flexure, where circumference was 6 2 cm Dilatation then progressively less to point 118 cm from duodenojejunal flexure, where circumference of ileum was only 1 2 cm Terminal 46 cm of ileum unexpanded but contained little meconium of normal consistence Ileum proximal to this contained brownish green meconium of normal consistence Colon and rectum about 38 cm long Cæcum and most proximal part of ascending colon moderately distended with meconium of firmer consistence than in any other part of bowel Colostomy situated just beyond hepatic flexure Colon distal to colostomy contained little meconium of normal consistence Except for most proximal part of ascending colon, average diameter of large bowel was about 1 8 cm All the intestinal tract was freely patent

Blocks taken from consecutive levels of the entire intestinal tract from hypopharynx to anus were examined histologically Inflammatory changes, mainly of the peritoneum, were fairly widespread and led to œdematous thickening of the bowel wall Intramural ganglia were normal in the œsophagus, the stomach, and the proximal part of the duodenum, but scanty and small in the distal part of the duodenum

The plexuses including both ganglion cells and nerve fibres were completely absent from all sections from the level of duodenojejunal flexure to the anal margin A representative photomicrograph is shown in fig 10 It is noteworthy that dilatation of the bowel wall extended well into the parts without intramural plexuses Paravertebral sympathetic ganglia and ganglia in the bladder wall were normal. Normal nerve bundles were found in random sections taken through the mesentery of the small and the large gut The pancreas was histologically normal

We can only speculate on the relationship of this condition of agenesis of intramural plexuses to Hirschsprung's disease It may well be a severe variant of the disease, and this view is supported by the observation of normal ganglia in both conditions in a proximal part of the intestinal tract, gradually disappearing towards the pathological segment

The aganglionic segment was, however, considerably longer than in any of the reported cases of Hirschsprung's disease, and, in contradistinction to the typical case, there were no nerve bundles in the affected part of the intestine

This case might illustrate a very early disturbance of the craniocaudal differentiation of intestinal neurones before the growth of nerve fibres into the bowel wall

Summary

We have presented the first study of the familial incidence of Hirschsprung's disease The evidence supports a genetic determination of the disease The over all chances of a male sibling of a known case being affected are about 1 in 5, those of a female sibling being effected are small

We have produced a follow up report of 37 cases treated by rectosigmoidectomy

A pathological study of our 40 cases has uniformly confirmed the previously reported absence of intramural ganglion cells, and the presence of abnormal nerve bundles in the terminal undilated segment of bowel A review of published reports shows that the length of the involved segment varies considerably The bulk of the reported cases (over 90%) show pathological changes in the rectum and part or all of the sigmoid colon Less than 10% have extremely long abnormal segments which appear to be incompatible with life if untreated

A case is reported showing a hitherto unrecorded condition of agenesis of both nerve fibres and ganglion cells of the intramural plexuses distal to the duodenojejunal junction Its possible relationship to Hirschsprung s disease is discussed

A theory is suggested to explain the histopathological findings in Hirschsprung's disease and its variants

We wish to thank the medical and surgical staff of the Hospital for Sick Children Great Ormond Street, for access to their patients, Dr S Lawler and Dr I A B Cathie for determining the blood groups of the twins, and Dr Eliot Slater for the opinion on the fingerprints of the twins in family 36 Our thanks are due to Mr Derek Martin, of the Department of Medical Illustration, for the photographs and the diagrams which were drawn by Mr P G Cull

RELATION OF PENICILLIN SENSITIVITY IN STAPHYLOCOCCI TO CLINICAL MANIFESTATIONS OF INFECTION

J C SHERRIS
M.D Lond
LATE ASSISTANT PATHOLOGIST, AYLESBURY PATHOLOGY LABORATORY

M. E FLOREY
M.D Adelaide
OF THE CHRONIC INFECTIONS UNIT, STOKE MANDEVILLE MINISTRY OF PENSIONS HOSPITAL

AYLESBURY, BUCKS

IN the past three years several bacteriological laboratories have reported an increasing incidence of penicillin resistant strains of *Staphylococcus pyogenes* in their routine work, and some writers have concluded that the clinical value of penicillin is steadily diminishing It seemed worth while, therefore, in a laboratory serving both an urban and a rural area, to see whether a clear cut distinction could be established between penicillin-sensitive and penicillin resistant strains of staphylococci, and, if so, whether this distinction was reflected in the clinical manifestations of infection in the lesions where they were found

The material for the inquiry was collected between November, 1948, and May, 1950, some from practitioners and two general hospitals, but mostly from a Ministry of Pensions hospital containing special units for plastic surgery, paraplegia and chronic-wound infections The great majority of the patients from whom the material was obtained had previously received penicillin treatment in one form or another, and the paraplegic patients had had many courses Special study of the signs of inflammation associated with these organisms was confined to the Ministry of Pensions Hospital Once it was found that the results of the bacteriological studies were consistent irrespective of the source of the staphylococci only lesions containing these organisms in the chronic infections unit were studied

BACTERIOLOGICAL INVESTIGATION

Methods

Detailed investigations were made on the first 156 strains isolated These were consecutive strains isolated in the laboratory during the period of the investigation excluding only those obtained from healthy carriers or on more than one occasion from the same lesion When an apparently representative collection from all sources had been obtained and the results were found to be consistent, segments extending to the anal margin, which is the typical finding in Hirschsprung's disease Ganglion cells which were in the process of formation at the time of onset of the disturbance would be imperfect (ganglia in transitional zone)

We have found no evidence in our histological material that the pathology is one of degeneration of previously formed ganglion cells, since reactionary changes, cellular infiltration, and fibrosis were not observed

It is the accepted anatomical teaching that the ganglion cells of the intramural plexuses relay parasympathetic fibres, and that the sympathetic fibres pass through the plexuses uninterruptedly, having been relayed in the abdominal sympathetic ganglia We postulate that the preganglionic parasympathetic nerve fibres, failing to terminate at a ganglion cell, grow caudally between the muscle layers and in the submucosa for a considerable distance Thus nerve trunks would be formed in the aganglionic segment consisting mostly of these fibres with a normal component of sympathetic fibres One would expect the nerve trunks, as they include increasing numbers of nerve fibres in the more distal parts of the aganglionic segment, to increase in density and ultimately in size, and this is in fact what has been found

Agenesis of the intramural ganglion cells would thus be the primary pathology, and development of abnormally dense and large nerve trunks, consisting of normal autonomic nerve fibres, a secondary phenomenon

The 3 reported cases of zonal absence of ganglion cells with normal ganglia both above and below cannot be simply explained on the basis of this hypothesis alone The occurrence of this rare variant suggests that sometimes, in addition to the craniocaudal differentiation of intramural intestinal neurones, there is a caudocranial differentiation with a final link up between the two A disturbance sometime before the completion of differentiation would explain the finding of zonal agenesis with normal ganglia both above and below

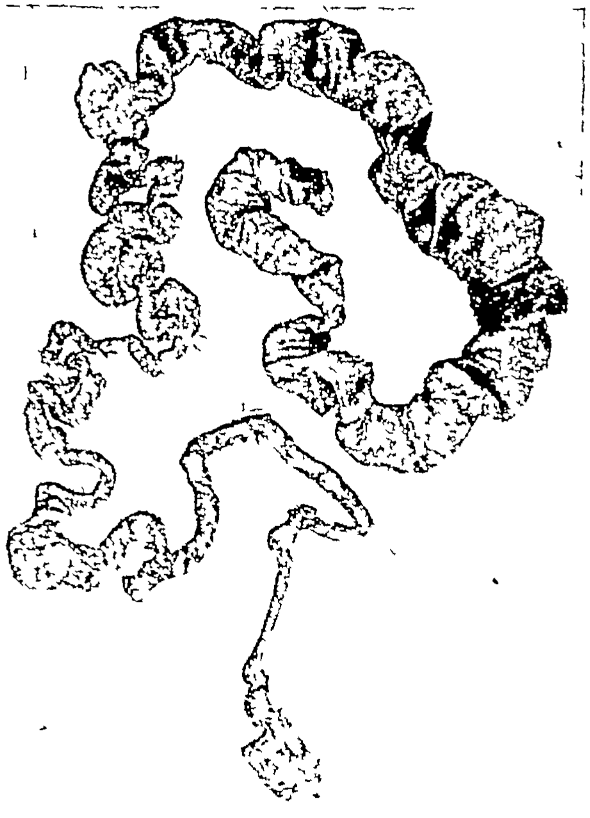

Fig 9—Intestinal tract from duodenojejunal junction to anal margin in a case of agenesis of intramural plexuses

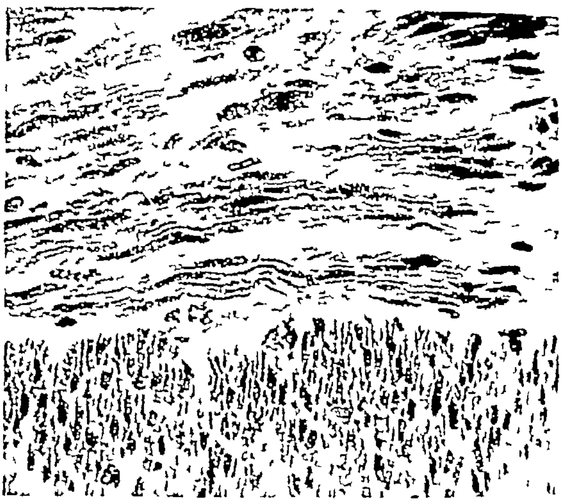

Fig 10—Representative section of bowel wall in agenesis of intramural plexuses (same case as fig 9) (× 300)

Our hypothetical view of the development of Hirschsprung's disease is purely theoretical and was produced in an attempt to explain the histopathological observations Recently, however, Prof J D Boyd kindly drew our attention to the work of van Campenhout (1931), who demonstrated in chick embryos that differentiation of intestinal neurones in the foregut preceded that in the hindgut, he also claimed that the intramural ganglion cells probably developed as an outgrowth of the thoracolumbar neural crest, and that the vagus played no part in their formation

A Case of Agenesis of Intramural Plexuses

The case reported below may possibly be a particularly severe variant of Hirschsprung's disease (see fig 9). We have not been able to find any published report of this condition

A boy, aged 4 days, an only child, was admitted to the Hospital for Sick Children under Mr G H Macnab, with complete intestinal obstruction from birth He vomited every feed, and throughout his life his bowels did not open. Abdominal distension was at first slight

Laparotomy at the age of 4 days revealed dilated loops of small intestine The distended parts tapered gradually away into an undistended terminal ileum without any sign of localised obstruction The whole length of the large intestine was completely undistended but contained a small quantity of meconium as far as the mid point of the descending colon. The meconium in the small intestine was apparently semi fluid A rubber catheter was passed per rectum and could be guided under vision into the descending colon No further interference seemed indicated, and the abdomen was closed

In view of the fact that no meconium had passed and the abdomen was increasingly distended, the abdomen was reopened on the seventh day of life Distension of the collapsed gut had proceeded a little further Ileo transverse colostomy was considered, but in view of the child's poor condition only a transverse spur colostomy was established.

The child's condition deteriorated, and he died at the age of 10 days without having passed meconium

Necropsy revealed moderate dilatation of the right atrium and ventricle in the heart, confluent lobular collapse, hypostatic congestion and œdema of the lungs localised fibrinopurulent peritonitis a very fatty liver, a normal pancreas, and the following changes in the gastro intestinal tract (fig 9) Œsophageal mucosa much congested Stomach moderately dilated, containing recent and altered blood mixed with mucus Duodenal contents deeply bloodstained Approximate total length of the jejunum and ileum, 164 cm First 27 cm of jejunum mildly dilated but not hypertrophied. Progressive dilatation of slightly thickened small bowel up coliform bacilli, or non hæmolytic streptococci, because their presence did not significantly affect the incidence of the specified signs of inflammation The presence of diphtheroid bacilli and micrococci was ignored In 2 of the patients studied pyrexia was discounted because both had severe urinary infections as well as the lesions from which the staphylococci were isolated, which were trophic sores free from pus or surrounding inflammation

Clinical Findings

The types of lesions from which the strains were isolated are shown in table II the numbers of each type in the whole series are shown in column A, and those in which the clinical manifestations of infection were studied and analysed statistically in column B It will be seen that those in column B form a fairly representative sample In each column the lesions are divided into those infected with sensitive and with resistant staphylococci The lesions have then been arranged in three groups, according to the penicillin sensitivity of their staphylococci, group I being those in which sensitive organisms predominate, group II those with predominantly resistant organisms, and group III those where the proportions were about equal.

It will be seen that the lesions in the first two groups are in the main distinct Group I, with 56 lesions, from 50 of which sensitive staphylococci were isolated, includes all the acute and originally closed lesions and all the chronic bone infections The resistant staphylococci in this group were obtained from (*a*) a perinephric abscess in a paraplegic patient admitted for a chronic urinary infection from which a penicillin resistant staphylococcus had been isolated, (*b*) a case of chronic suppurative arthritis, also in a paraplegic, and (*c*) 4 cases originally admitted for chronic osteitis which acquired a resistant infection after admission to hospital Group II contains 84 lesions, 78 of which yielded resistant staphylococci, it is mainly composed of infected operation wounds, superficial trophic lesions in paraplegic patients, burns, and other open traumatic lesions, and low grade puerperal infections where the staphylococci were isolated from the patient's cervix In the 4 cases of long-standing sinuses the organisms were isolated from the mouths of the sinuses, which were too narrow for the swab to be inserted without touching the skin, staphylococci were not isolated on subsequent occasions

TABLE III—INCIDENCE OF CLINICAL SIGNS OF INFLAMMATION IN LESIONS INFECTED WITH PENICILLIN SENSITIVE AND PENICILLIN RESISTANT STRAINS

Penicillin sensitivity of staphylococci	Total lesions*	Inflammatory signs absent	Inflammatory signs present		
			With pus	Without pus	Total
Sensitive	57	9	34	14	48
Resistant	78	43	21	14	35

$\chi^2 = 22\ 60$ P $< 0\ 001$

* Exclusions explained in text.

In group III, where little distinction could be drawn between those with sensitive and with resistant staphylococci, the lesions were largely superficial ones, such as ulcers, dermatitis, and soft tissue sinuses

A statistical analysis of the clinical findings (table III) shows that manifestations of inflammation were noted in 48 of the 57 lesions from which penicillin sensitive staphylococci were isolated (i e, 84%) but in only 35 of the 78 lesions yielding penicillin-resistant strains (i e, 45%) Suppuration was noted in 60% of the penicillin sensitive group but in only 27% of the penicillin-resistant group In each case the difference is statistically significant The signs of inflammation were absent in 9 of the 57 lesions yielding sensitive staphylococci compared with 43 of the 78 yielding resistant strains—i e, 16% as against 55%

DISCUSSION

The published work on the penicillin sensitivity of staphylococci was reviewed by Florey et al (1949), and our findings confirm several previous contentions They showed that resistant staphylococci might be divided into (1) naturally resistant or penicillinase producing organisms, (2) those with resistance acquired in vitro, associated with diminution of virulence, slower growth than the original strain, and inability to produce penicillinase, (3) those with resistance acquired in vivo They considered that those reported as falling into the third group resemble naturally resistant staphylococci which have never been in contact with penicillin rather than those which have become resistant in vitro They concluded that there was no conclusive evidence that staphylococci can become resistant by more than one mechanism Despite the fact that many patients in the Ministry of Pensions Hospital had chronically infected open wounds which had been treated liberally with penicillin, no resistant non penicillinase producing strains, such as might result from resistance acquired in vivo, were found in the swabs from this hospital

Bondi and Dietz (1945) and Forbes (1949) found that the penicillin sensitivities of the non penicillinase producing strains they isolated all fell within a limited range A similar sharp distinction between resistant and sensitive strains was noted in the present investigation the bacteriological observations were restricted to the primary isolation and plate tests for penicillin sensitivity

The swabs received were inoculated on blood agar plates, aerobically and anaerobically, and also on segments of 'Cetavlon' and 7% salt agar plates In some cases the swab was then cut off into Robertson's cooked meat medium

Strains of *Staph pyogenes* were tested for coagulase production on primary isolation by the slide method of Cadness Graves *et al* (1943), or, when the results of this test were equivocal, by the tube method of Fisk (1940)

Tests for penicillin sensitivity were then made by streaking an inoculum of four or five colonies across half a ditch plate A single control streak of the Oxford staphylococcus was made across the centre and a second organism streaked across the other half The ditch contained 10 units per ml of penicillin incorporated in the agar The plates were incubated for 16–24 hours and read in the morning All strains reported sensitive showed an even band of inhibition on either side of the ditch approximating to that of the Oxford staphylococcus, those reported resistant grew up to or over the ditch at the site of heaviest inoculum, with an increasing zone of inhibition as the inoculum became dilute, but in no case was the zone as great as that of the Oxford staphylococcus This latter appearance was described by Barber (1947) as characteristic of penicillinase producing strains, and is in contrast to that of organisms resistant to penicillin but not destroying it, where growth proceeds evenly up to, or over, the ditch

The strains were kept for detailed bacteriological study of penicillinase production or quantitative assessment of sensitivity by subculturing from the original plate on to broth agar slopes, and were maintained in stock culture under liquid paraffin by the method of Morton and Pulaski (1938) After the period of collection all but 3 of the sensitive strains were recovered from stock culture and were tested quantitatively for penicillin sensitivity by the following method

To ensure uniform conditions for all strains, 60 ml quantities of broth containing commercial crystalline penicillin G in concentrations of 0 0025, 0 005, 0 01, 0 02, 0 04, 0 08, and 0 16 unit per ml were distributed in $3 \times {}^{1}/_{2}$ in tubes in 1 ml amounts A set of these tubes for each sensitive organism was inoculated with 0 025 ml of a 1/100 dilution of an overnight culture of its respective staphylococcus One set received a similar inoculum of the Oxford staphylococcus In two instances the turbidity of the overnight culture, as judged by the naked eye, was less than that of the Oxford staphylococcus, and the dilution of these cultures was modified appropriately

All the tests were incubated simultaneously at 37°C for 18 hours, and the first tube showing no turbidity to the naked eye was taken as the end point In all cases this was clear cut

All but 8 of the resistant strains were recovered from stock culture, and these, together with the sensitive strains, were tested directly for penicillinase production by a method similar to that described by Bondi and Dietz (1944)

Plates inoculated with the Oxford staphylococcus were prepared according to the cylinder plate method of Heatley (1944) Into the cups were pipetted equal quantities of penicillin solution containing 5 units per ml and of overnight cultures of the staphylococci A control cup on each plate contained equal quantities of the penicillin solution and of an overnight culture of the Oxford staphylococcus The plates were incubated overnight at 37°C and the diameter of the zones of inhibition round the cups measured next morning

No attempt was made to assess quantitatively the resistance of penicillinase producing strains, because Kirby (1945) and later workers (see Florey et al 1949) have shown that the end point obtained depends on the size of the inoculum

Results

Of the 225 strains of *Staph pyogenes* isolated from 224 lesions, 97 were reported "sensitive" and 128 "resistant" by the plate method From one bedsore both sensitive and resistant staphylococci were isolated from the primary plate

On direct testing for penicillinase production the difference between the two varieties was distinct, for no zone of inhibition was produced round the cups containing the "resistant" staphylococci, whereas the cups containing the "sensitive" staphylococci were surrounded by a zone of inhibition whose diameter was in every case within 0 3 cm of that surrounding the control cup containing the Oxford staphylococcus The diameter of the zone of inhibition around this control cup varied between 2 2 and 2 5 cm, with an average value of 2 4 cm Quantitative testing of the "sensitive" strains demonstrated that all produced an end point of inhibition within the range examined These results are set out in table I

TABLE I—PENICILLIN SENSITIVITY OF 145 OUT OF 156 CONSECUTIVE STRAINS OF STAPHYLOCOCCI RECEIVED AT THE LABORATORY

55	4	7	33	10	1	90

3 sensitive and 8 resistant strains were lost in stock culture

All the strains examined could thus be divided sharply into two classes—(1) resistant or penicillinase producing, and (2) sensitive or non penicillinase producing—all the sensitive class falling within a limited range of sensitivity between 0 005 and 0 08 unit per ml. under the conditions of the test (The Oxford staphylococcus was sensitive to 0 02 unit per ml)

CLINICAL INVESTIGATION

Methods

In the chronic infections ward routine swabs were always taken on the patient's admission and thereafter once or twice a week Notes were made on the presence or absence of signs of inflammation before the bacteriological findings were known In the rest of the hospital swabs were taken as the doctor in charge of the case thought necessary

On receipt of the laboratory report each patient in the group investigated clinically was visited by one of us and information was also obtained from the ward staff Further visits were made to assess the progress of the lesion and its relation to the presence of staphylococci. In some cases the information was not complete and this is reflected in the different totals in the tables

Records were kept of the type of each lesion, and at each visit the presence or absence of the following signs of inflammation was noted (1) erythema, œdema, and tenderness around the lesion, (2) pus formation, and (3) pyrexia In some cases—notably deep seated infections in paraplegics—it was not possible to demonstrate the first of these signs No attempt was made to assess the manifestations of infection quantitatively because of the wide differences in the severity of the lesions, depending on their site, extent, and duration and their reaction after penicillin was administered The investigation was solely concerned with the presence or absence of the specified signs of infection during the time the staphylococci were known to be present

Exclusions

The 31 lesions infected with β hæmolytic streptococci in addition to the staphylococci were excluded from the clinical assessment, as were 50 cases in various hospitals and general practices beyond the reach of the clinical investigator and 9 others in which complete information on all the criteria could not be obtained The remaining lesions, which were *included in the statistical analysis*, totalled 135

We have not excluded lesions in which there was additional infection with *Ps pyocyanea, Proteus vulgaris,* fossa and groin. The loss was large for three days and attacks came every few minutes she had the feeling that her insides were being pressed down into the vagina, and she was doubled up with pain No medicines had been effective She had no frequency of micturition Her appendix was removed 4 or 5 years ago, but this made no difference to the severity of her attacks She had been advised to have her uterus removed

Examination—Her physique was excellent, and no abnormality was found on general examination Pelvic examination, without an anæsthetic, showed that her uterus was anteverted, small but not infantile of the type often found in nulliparous women of her age The ovaries were both palpable, but not tender A point to the right of the fundus uteri, but distinct from both ovaries and uterus, was acutely tender to gentle bimanual palpation No other evidence of disease was found Pelvic examination under anæsthesia revealed no abnormality

Cystoscopy and Pyelography—Cystoscopy showed marked pseudomembranous trigonitis and basal cystitis Catheters passed easily into the ureters The Braasch bulb size 16 was tight size 22 met with firm resistance to extraction, particularly on the right Gradual dilatation to Braasch 24 was successful On extraction of the bulb, white stringy flecks of mucosa came out of the ureter, probably from an extension of the pseudomembranous patches in the bladder The ureters were tortuous and irregularly dilated, indicating chronic ureteritis The right renal pelvis was dilated and the emptying film showed a large residue of dye There was no renal ptosis Urine taken during the examination was normal and sterile Recovery was complete in 24 hours the patient left hospital 36 hours after her admission

Result—Since the dilatation of the ureters, there has been no pain or discomfort with menstruation. The mental and physical effect upon the woman has been dramatic

Case 3—Mrs C, aged 25, married 4 years, no children

Symptoms—Her menses started at the age of 15, but then stopped for 6 months At 16 they became regular, with no discomfort After her matriculation she experienced some pain at her periods It gradually increased until at 19 she had to go to bed immediately she started menstruating Standing or walking aggravated her discomfort and she felt that her "insides were dropping out" A variety of medicines and hormone treatments did not relieve her, nor did physiotherapy Dilatation and curettage had no effect Because of the fixed idea that she was imperfectly made, she refused to become pregnant, and she became terrified of childbirth

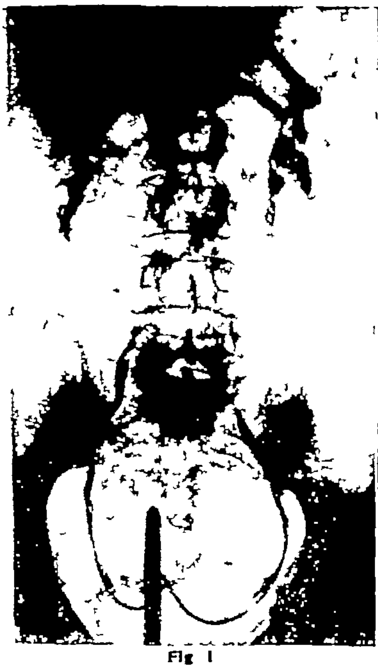

Fig 1

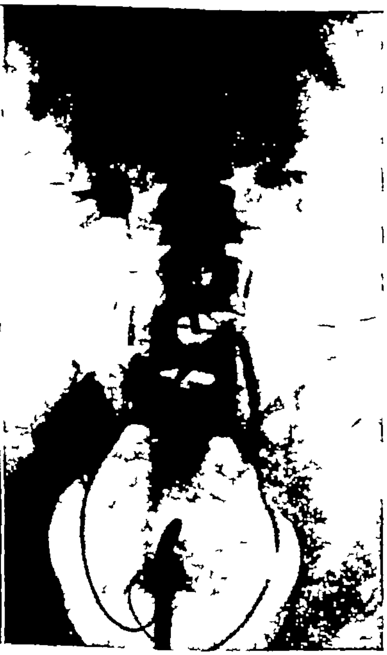

Fig 2

Fig 1 (case 1)—Right ureter is kinked opposite the 2nd lumbar vertebra Irregularly dilated and tortuous. The pain was more severe on the right side

Fig 2 (case 3)—Dilatation and tortuosity more marked on left—the side on which the pain was severe.

The pain was spasmodic and severe, chiefly in the left side and in the left iliac fossa but sometimes in the back There was no frequency of micturition but she had found that if she retained her urine for any length of time the pain worsened She complained of deep dyspareunia and 2–3 hours pain, simulating her menstrual pain, after orgasm at any phase of the intermenstrual cycle

Examination—The only abnormality found on general examination was slight ptosis of the right kidney Vaginal examination showed a small and antiflexed uterus, the right ovary was prolapsed but not tender, the left ovary was palpable high up, without discomfort There was a localised area of tenderness to the left of the body of the uterus where bimanual palpation caused pain "similar to menstruation"

Cystoscopy and Pyelography—Cystoscopy showed trigonitis, spreading up to and involving both ureteric orifices Catheters passed freely into and up both ureters Retrograde pyelography revealed bilateral ureteritis, the left ureter being more affected than the right (fig 2) In the erect posture there was considerable ptosis of the right kidney but no ureteric kink The emptying picture showed that neither kidney retained any dye Braasch bulbs met with some resistance, but the pelvic ureter was gently dilated to receive size 24 Recovery was complete in 24 hours

Result—Since the ureters were dilated, menstruation has been entirely free from the left sided spasmodic pain There is no longer dyspareunia or pain after orgasm After "that awful pain" went she developed an entirely different outlook on life and wanted to be told all about childbirth. I have recently heard from her that she is pregnant and very happy

DETAILS OF PROCEDURE

Before discussing these cases it may be well to state precisely how the investigation was made

The patient was anæsthetised with sodium thiopentone on a urological operating table so that the X ray pictures could be taken as soon as the investigator said the word Dr Ernst Widrich performed the urological investigations for me, and Dr I A. Brotman the radiological examinations The order of procedure was as follows

1 Vaginal examination
2 Cystoscopy A specimen of urine was collected in a sterile container
3 *Ureteric catheters passed*
4 Control film taken
5 Injection of 5–6 ml 12 5% sodium iodide into each ureter
6 Filling picture taken
7 Catheters withdrawn Dilatation of the ureters with Braasch bulbs up to size 22–24 (according to resistance)
8 Table rotated into vertical position for erect picture
9 Emptying picture taken in horizontal position

The films are developed immediately and unless there is any indication for further investigation the whole procedure occupies a maximum of 20 minutes If there is any evidence of infection 4–5 ml of 2% Argyrol is instilled into each ureter, and intramuscular penicillin (500,000 units) is given in a single intramuscular dose If it is believed that infection is due to a penicillin resistant organism, streptomycin 0 5 g may be given 6 hourly for 24 hours Most patients have little or no postoperative discomfort and return home 36–48 hours after admission. Occasionally there is pain for 12–16 hours, which is treated with antispasmodics

DISCUSSION

About 3% of women suffer from intractable or disabling pain at the menses All pain in the human body is unnatural and has a cause "Physiological pain" is a contradiction in terms Wharton (1943a) follows accepted principles and divides dysmenorrhœa into primary and secondary types 'the term 'primary dysmenorrhœa,'" he writes, "is synonymous with essential, Evidence has been produced to show that resistant staphylococci are isolated more frequently from hospital inpatients than from the population at large Forbes (1949) found that the proportion of resistant strains in staphylococci isolated from lesions contracted outside hospital was 12 5% compared with 68 4% from those contracted inside Rountree and Thomson (1949) showed that, in their series of lesions associated with resistant staphylococci, 54 had been cross infected in hospital compared with 8 infected before admission Cairns and Summers (1950) reported that 78% of the staphylococci isolated from hospital infections were resistant to penicillin compared with 19% of those isolated from closed abscesses present on admission, moreover, the proportion of resistant strains isolated from patients admitted to hospital with open infections rose with increasing stay in hospital Barber et al (1949), investigating the carrier rate of staphylococci in a maternity hospital, found 70–80% of resistant strains among the staphylococci isolated from carriers but found none among staphylococcal carriers in a control group outside hospital

Less attention has hitherto been paid to the lesions associated with resistant and sensitive organisms and the clinical manifestations of infection with the two types In the present series penicillin sensitive staphylococci were mostly isolated from acute lesions closed till operation or from chronic bone infections, some of which were of long standing and due to gunshot wounds in the 1914–18 and 1939–45 wars Resistant staphylococci, on the other hand, were mainly isolated from postoperative wounds, half of which followed plastic repair, and from other superficial lesions such as trophic sores in paraplegic patients These results appear to support the view that the high proportion of penicillin resistant strains now being isolated in bacteriological laboratories is a result of either the high carrier rate of these organisms in hospital staffs or their greater chances of survival in an environment where penicillin abounds Our clinical analysis shows, however, that the high carrier rate is not a reflection of the relative incidence of resistant and sensitive strains present in serious inflammatory infections The specified signs of infection were found significantly less often in lesions yielding resistant than in those yielding sensitive staphylococci

In view of the different types of lesion with which they were associated, this result cannot be interpreted as indicating that the resistant strains were less virulent than the sensitive, but the difference in the inflammatory signs associated with the two types of infection may help to bring into perspective the clinical importance of the reports of an increasing incidence of penicillin resistant staphylococci

CONCLUSIONS

In this study there was a clear bacteriological distinction between penicillin sensitive and penicillin resistant staphylococci All sensitive strains were of the same order of sensitivity as the Oxford staphylococcus and all the resistant strains produced penicillinase

The two types of staphylococci were in the main associated with different types of lesions—the penicillin sensitive strains with acute and closed or deep seated infections, whether acute or chronic, the resistant strains with superficial lesions

The penicillin resistant staphylococci were significantly less often associated with signs of inflammation or suppuration than the sensitive strains

We wish to thank the many doctors who gave us their permission to carry out this investigation on their patients Dr A Wilson for continuing the routine bacteriological examination after one of us (J C S) had left the laboratory, the ward sisters of Stoke Mandeville Ministry of Pensions Hospital for their willing coöperation in obtaining data, Miss Randall and Miss Ridley Thompson for the typing We are also indebted to Mr P H Leslie for the statistical analysis of the figures obtained, and Dr R L Vollum for his criticisms of the bacteriological section

URETERIC DYSMENORRHŒA

GRANTLY DICK READ
M.A., M D Camb

THREE cases of intractable pain at the time of the menses are recorded here as examples of one type of dysmenorrhœa The origin and nature of the pain are discussed, and a method of investigation and treatment is suggested

CASE RECORDS

Case 1 —Mrs A, aged 36, no children, 8 week abortion 10 years ago, no other pregnancy

Symptoms —Menstruation was preceded by backache for several days and she suffered from lassitude and depression. At first the pain was suprapubic and extended across the lower abdomen It was most severe on the right, and extended upwards around the right loin there were exacerbations every few minutes, which doubled her up This phase of the menses was accompanied by distension of the abdomen, a sensation of pressure and fullness in the vagina, and sometimes frequency of micturition There was a bright red loss for one day, followed by drainage for anything up to ten days.

Examination —She was a thin, alert, healthy, and active woman. A slight, low dorsal scoliosis, and ptosis of the right kidney were the only abnormalities found on general examination Pelvic examination both with and without an anæsthetic revealed nothing that could account for her symptoms. Her urine was normal

Intravenous pyelography showed ptosis of the right kidney associated with kinking of the ureter immediately below its junction with the renal pelvis Both ureters were tortuous and irregular in outline

Cystoscopy and retrograde pyelography showed mild trigonitis. The ureteric catheters passed easily The right ureter was dilated with Braasch bulbs up to size 22 The left kidney was normal in position, and the left ureter less affected than the right (fig 1) Radiography in the erect position demonstrated that the right kidney dropped into the right iliac fossa Urine collected during the investigation was normal, and sterile

Treatment —Nephropexy was undertaken, using Demmings's method of slinging by closing the lower opening of the perinephric capsule The sympathetic nerve supply was interrupted by stripping the renal artery back to the aorta, and also stripping the upper end of the ureter Recovery from the operation was uneventful

Result —Since the operation, all menstrual periods have been free from pain There has been no premenstrual backache, lassitude, or depression The menstrual flow lasts for 3–4 days only, and ceases abruptly She has put on 5 lb in weight and can walk 2–3 miles without backache or fatigue She no longer dreads her menses and reports that her outlook on life is entirely different

Case 2 —Mrs B, aged 43, no children, one miscarriage about 15 years ago

Symptoms —From the menarche at 13 she had always had some discomfort at menstruation For the last 20 years it had been worse, and for the last 10 years she had had very severe pain which came on with the menstrual flow She dreaded the beginning of menstruation

The pain was suprapubic at its onset extending across the lower abdomen to the right iliac fossa but not to the posterior renal area There was some stabbing pain in the left iliac issues of that ureter will record the greater sensory eaction and take precedence over the afferent response of the uterus and the other ureter, in keeping with Sherrington's (1906) theory of the common path The converse occurs when the ureters are healthy and the uterus is disorganised by disease

The fear tension pain syndrome can be arrested by eliminating either the psychic or the somatic causes The pain can be relieved by drugs and analgesics The psychiatrist can break down the syndrome by psychic rectification and the therapeutic implantation of rational fear destroying mental processes Destructive operations, such as presacral sympathectomy or hysterectomy, can be performed This is applicable both to ureteric tension and to certain forms of dysmenorrhœa which are associated with spasm of the uterine musculature If presacral sympathectomy is performed, the nerves which convey psychic stimulus are removed and therefore the tension is not increased by efferent discharges The same syndrome can also be broken down by stretching the spastic muscles But the mechanism of relief by dilatation requires further explanation

Relief by Dilatation

Dilatation of constricted orifices in the body often relieves spasmodic pain temporarily, though it does not remove the cause The extent of tissue destruction from careful dilatation is negligible no structural change takes place that could prevent a recurrence of spasm after a short time, and indeed if these cases are treated purely by surgical procedures without attention to the patients' mental attitude many have a recurrence of pain after 2–3 months Wilfred Shaw (1948) writes “It is difficult to understand why dilatation of the cervix cures the pain in spasmodic dysmenorrhœas” Dilatation does not cure it is an important accessory to relief The stretching of the circular muscle fibres and connective tissues prevents painful spasm for a short time and establishes confidence that the dysmenorrhœa is relieved. The menses are no longer feared and the efferent sympathetic nerves do not, through emotional excitation disturb the normal harmony of action of the longitudinal and circular muscle fibres that produce painless peristalsis This offers an explanation for Wharton's (1943b) statement “If one can give the young woman a few months of relief from dysmenorrhœa she may have no more trouble from it and require no more attention” Excessive tension and spasm does not recur in women when the primary cause has been psychogenic, therefore pain is absent when the fear of pain has been obviated by painless menses If through psychic stress anxiety again becomes established pain will return Dilatation of the ureters will have to be repeated and psychological rectification again undertaken, until the bases of her fears have been eliminated.

SUMMARY AND CONCLUSIONS

Three cases of intractable incapacitating dysmenorrhœa are recorded, in which there was no evidence of uterine or ovarian disease. Stricture or spasm of one ureter was diagnosed in each case, and treatment of this condition resulted in complete relief from menstrual pain

Cystoscopy and retrograde pyelography should be a routine procedure in the investigation of intractable dysmenorrhœa Hysterectomy or presacral sympathectomy should not be advised until the urinary tract has been examined.

Dysmenorrhœa is often the somatic manifestation of a psychological state, resulting in the fear tension pain syndrome

I wish to express my thanks to Dr Widrich and Dr I A Brotman both of Johannesburg, for collaborating with me in these investigations

CHANGES IN BLOOD CHEMISTRY AFTER SURGICAL OPERATIONS

A W Wilkinson
Ch.M Edin, F R C S E

Barbara H Billing
B.A. Camb, Ph.D Edin

Gabriella Nagy
B Sc Lond

C P Stewart
M Sc Durh, Ph.D Edin

From the Department of Surgery, in the University of Edinburgh, and the Clinical Laboratory, Royal Infirmary, Edinburgh

In a study of the effects of surgical operations on nitrogen and electrolyte metabolism (Wilkinson et al 1949, 1950) it was shown that immediately after operation the urinary excretion of nitrogen and potassium was increased, whereas that of sodium and chloride was decreased This appeared to be a fundamental part of the body's response to injury and to be independent of the type of surgical operation, it was not abolished by dietary measures Whether or not corresponding changes took place in the composition of the blood seemed to be worth investigating, and the results obtained from 30 patients, studied in two groups, are reported here

METHODS

Group I comprised 4 healthy volunteers who acted as controls by submitting to dietary restriction but not to surgical operation, and 20 male patients who underwent surgical operation Of the latter, 17 were submitted to partial gastrectomy, and 1 each to gastro enterostomy, splanchnicectomy, and vagotomy plus gastrectomy

Blood was withdrawn at least once before and again two days, four days, and fourteen days after operation In some cases more frequent sampling was possible during the postoperative period In all cases blood was withdrawn without stasis into a glass syringe sterilised by autoclaving, transferred to tubes containing any necessary anticoagulant, and analysed without delay In most samples determinations were made of plasma-proteins (micro-Kjeldahl, with magnesium sulphate as the fractionating agent), non protein nitrogen (micro-Kjeldahl), chloride (Van Slyke 1923), and carbon dioxide combining power (Van Slyke and Cullen 1917) In some cases, limited unfortunately by the undesirability of repeatedly withdrawing large samples of blood, some or all of the following were also determined serum sodium (Peters and Van Slyke 1931), urea (Van Slyke 1929), amino acid nitrogen (Frame et al. 1943), creatinine (Folin and Wu 1919), and uric acid (Folin 1930) Determinations of hæmoglobin were made by the carboxyhæmoglobin method with a Haldane hæmoglobinometer calibrated so that 100% represented 14 8 g of hæmoglobin per 100 ml. of blood

idiopathic, intrinsic or functional dysmenorrhœa" Fluhmann (1939) prefers the terms intrinsic and extrinsic In point of fact, however, there is no such entity as primary or intrinsic dysmenorrhœa menstrual pain is secondary to definite pathological disorders But these are not necessarily uterine, the disorder may be located elsewhere—even at the psychological level

These three cases, which are examples of a large category, call attention to a postulate which cannot be too frequently stated—that gynæcology is the science of the whole woman Manifestations of disease in the female organs or reproductive function may be primary and local, but they may also be secondary to the disorganisation of almost any physiological function in the body Psychological factors are, of course, of supreme importance

The three patients had received all the usual medical and surgical treatments Pain relieving drugs, hormones, sedatives, and tonics had been exhibited without appreciable benefit Each patient had undergone dilatation and curettage before consulting me Two of them had had their appendices removed, but no evidence of inflammation was reported Presacral sympathectomy had been advised in all three cases, and the two elder women had been urged to undergo hysterectomy But none of them had been cystoscoped or had the urinary tract examined

Pain of Ureteric Origin

No tumour, neoplastic change, or inflammation could be found to account for their intense pain, which was spasmodic, severe, and incapacitating, and occurred only at the onset of menstruation The site and nature of the pain were the same in all three cases

Hunner (1928), in his outstanding paper, "What the gynecologist should know about urology," recorded this form of dysmenorrhœa He attributed it, however, to inflammatory stricture of the ureter, which does not explain many of the associated phenomena Morison (1942) refers to these manifestations of ureteric spasm but puts the pain not at Morris's point but in the broad ligament zone, and appears to regard infection as the main ætiological factor This is a mistake Speransky (1935) is right when he says that "in our diagnosis we actually fasten on the result and do not take into account the mechanism of the pathological process"

It is not sufficient to ascribe spasm and stricture in one part of the ureter to inflammation without offering some explanation of the manner of infection Although direct or primary infection of the lumen of the ureter has been recorded by various authors, the inflammation which gives rise to stricture and spasm is intramural, and the infection is conveyed by lymphatics The lymphatics of the pelvic ureter empty into the hypogastric lymph-nodes, which also receive lymph from the cervix and the body of the uterus Segmental lymphatic drainage of the ureter is generally recognised, but Mackenzie and Wallace (1935) pointed out that free anastomosis may occur under certain conditions, allowing both ascending and descending intramural infection In this way the ureter may become infected from the cervix or body of the uterus, and Hunner's (1925) contention that ureteric stricture can arise from distant foci of infection, such as the teeth, tonsils, and sinuses, may be justified

Infection leads to inflammation, and the latter causes spasm The constriction may be acute, subacute, or chronic, according to the patient's ability to overcome the infection The local spasm may not be sufficiently severe to cause pain, for constrictions in the lower third of the ureter may be demonstrated by pyelography in women who have pain only at the menses that is to say, the constriction remains between the periods but only becomes painful with the onset of the menses This may explain the observations of Pelouze (1941) that Hunner claimed to have encountered clinically 2000 strictures in 8 years, whereas 479 necropsy specimens examined by five investigators failed to reveal a single primary stricture Is it not possible that in the relaxation of death macroscopic evidence of antemortem spasm may be obliterated? "Spasm simulating stricture may inject an element of confusion," say Lowsley and Kirwin (1944), and fibrous tissue appears in and about muscles in a state of persistent spasm

Spasm of smooth muscle is accompanied by vasoconstriction it is probably this that is responsible for the acute *intermittent* pain of ureteric dysmenorrhœa. Uterine spasm causes a dull suprapubic ache which extends across the lower abdomen and is not colic, but the relative ischæmia of the ureter is accompanied by pain which increases in intensity with each peristaltic wave Langley and Anderson (1895–96) demonstrated ischæmia of pelvic viscera on stimulation of the hypogastric nerves, and Lewis (1932) showed that severe and paralysing pain develops in muscles with restricted blood supply Peristalsis in the ureter is not arrested by focal areas of intramural infection, although local spasm confines the infective agent

Psychosomatic Aspects of Dysmenorrhœa

The psychological effect of menstruation has been discussed by a very large number of workers, most of whom agree with Naber (1931) that "dysmenorrhœa is generally of psychogenic origin" Dunbar (1938) gives an extensive bibliography of this subject Yet from all these published observations there is one omission—the ureter is not referred to The effect of psychic influences upon the uterus and its functions occupies the attention of all these authors, though there seems to be no explanation of the mechanism by which psychical influence can produce the results ascribed to it

The three cases I record here as examples of ureteric dysmenorrhœa exhibit many symptoms which previously have been considered uterine in origin, but which were eliminated by *treatment of the ureter* *Ureteric* peristalsis recurs at intervals corresponding to the attacks of colic complained of by the three women is any rhythmical uterine spasm recognised that could account for this phenomenon? All three spoke of a sense of fullness and dropping in the vagina, and this symptom, too, disappeared after dilatation of the lower third of the ureter

The fear tension pain syndrome (Dick Read 1946) is applicable to the inflamed pelvic ureter, which is supplied through the hypogastric plexus by the same nerves as, under emotional stress, give rise to the abnormal tensions, and therefore the pain, of labour The onset of menstruation, which is a continual reminder of the reproductive process, is not only accompanied by the fear of discomfort, but wakes up the underlying causes of anxiety associated with the whole reproductive function, which originated in what we will term "psychic trauma" at an earlier age the result is an overactivity of the *sympathetic nervous system out of all proportion* to the intensity of the afferent stimulus The already spastic ureter, which has been subjected, with the other pelvic viscera, to premenstrual congestion, receives a violent added stimulus, which causes such tension that the *threshold of pain is crossed* The vicious circle is thus established, for the presence of pain justifies the fear which, through the sympathetic nervous system, stimulates the circular smooth muscle fibres of the ureter, thereby increasing the tension and the pain, until a severe and incapacitating condition arises It may be asked why the ureter should give rise to pain if, through the hypogastric nerves, the uterus is subjected to the same efferent nervous discharges But if the uterus is healthy and one ureter is inflamed, the supersensitive

Chloride

The concentration of chloride in the blood usually fell slightly for the first day or two after operation, and thereafter rose until it was significantly higher than before operation In some cases the plasma chloride concentration showed a slight transient fall, but usually it was unaltered throughout the period of observation Calculation showed that the chloride concentration not only of the plasma but also of the erythrocytes was substantially constant, and that the changes in whole blood were due to changes in the relative proportions of plasma and cells

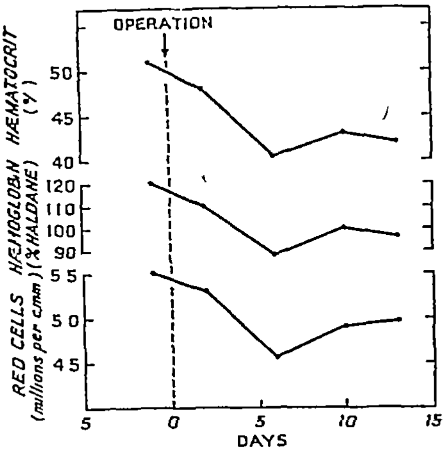

Fig 2—Changes in hæmatocrit and amounts of hæmoglobin and red cells after partial gastrectomy

Sodium and Potassium

In 3 or 4 patients the plasma sodium fell slightly, the average decrease being 17 mg per 100 ml. These changes were similar to those in chloride, but, as in the case of chloride, did not seem to be of sufficient magnitude to account for the marked decrease in urinary output of sodium in the days immediately following surgical operation

Potassium was determined in the serum in only a few cases There was no marked alteration in the post operative period, although there was at that time a very significant increase in the urinary output of potassium

The discordance between the plasma and urinary findings suggests that, whatever may be the initial cause of the metabolic disturbances, there is some interference with the normal renal control of the electrolyte balance Such an interference may be attributed to an increased production of adrenocortical hormones, indeed, several investigators claim to have demonstrated this

RESULTS IN GROUP II

Even more than at a later stage, on the day following operation the composition of the blood was liable to be disturbed by the intravenous administration of fluids Nevertheless certain general trends could be distinguished The data are summarised in the accompanying table

In all 10 cases the plasma volume was lower on the day following than on the day preceding operation, and although the amount of change was not always great it seemed to be real In 9 of the cases there was also some hæmoconcentration Evidently in addition to the loss of blood at operation (much of which was, in any case, replaced by blood transfusion), there had also been a loss, by some other route, of plasma This meant that, although the changes in plasma protein concentration observed at a later stage were not observed on the first day after operation, there was at that time an actual decrease in the total amount of circulating plasma protein This decrease was considerable, and averaged about 16% of the calculated preoperation quantity (range 8 2–29 7%), it was in many cases far too large to be explained entirely by loss of whole blood at operation Moreover the decrease in circulating protein was disproportionately a decrease in albumin Infusion experiments have shown that plasma proteins are metabolised slowly, and on this basis the observed decreases are too large to be explained by oxidation. The protein, accompanied by plasma water, must have left the circulation for some other fluid compartment The same conclusion may be drawn from the similar decreases in the total amount of chloride and sodium ions in the circulating plasma—decreases which were not paralleled by changes in concentration and which occurred at a time when urinary output of these ions had also decreased

The measurements of the "thiocyanate space," an attempt to determine the volume of extracellular fluid, were not entirely satisfactory The changes observed were never large, were inconstant in direction, and, in view of the inaccuracy of the procedure, were probably justly interpreted as insignificant The average for the 10 cases was a loss of 38 ml, compared with an average plasma loss of 478 ml This would mean (since the thiocyanate space is a measure of the total extra cellular space, including the plasma) a transference of plasma water and (though not necessarily wholly) certain plasma solutes, from the vascular space to the extracellular extravascular space

It is not to be supposed that there is a physical escape of plasma from the circulation, the changes in chemical

CHANGES IN BLOOD AND EXTRACELLULAR FLUID THE DAY AFTER OPERATION

Group II included 10 patients, of whom 4 were submitted to partial gastrectomy, 2 to gastro enterostomy, 2 to splenectomy, 1 to cholecystectomy, and 1 to nephrectomy In these, plasma proteins, serum sodium, and serum chloride levels were determined the day before and the day after operation Further, in an attempt to gain information as to quantities as well as concentrations, the plasma volume (Gibson and Evans 1937), and the thiocyanate space (Bowler 1944) were measured For these determinations 20 ml of blood was withdrawn by venepuncture, and then through the same needle 5 ml of 0 24% blue dye T 1824 was injected, followed by 10 ml of 5% sodium thiocyanate The exact amounts injected were determined by calibrating the syringes used for the amount they delivered from the 5 or 10 ml mark, in the case of sodium thiocyanate the fluid remaining in the needle after the injection was not included From a vein in the other arm 15 ml of blood was withdrawn ten and thirty minutes after the dye had been injected The blood was allowed to clot, and after an initial spinning the supernatant serum was spun again and used for the estimations The plasma volume was calculated from the concentration of T 1824 in the ten minute sample found by direct determination, and the thirty-minute sample, after suitable treatment, was used for determining the thiocyanate space The estimations were made with a Spekker photo electric absorptiometer, by comparison with standard solutions, water being the reference fluid in all cases The blood volume was calculated in the usual way from the plasma and hæmatocrit reading Corrections were not made in the hæmatocrit figures for plasma trapped in the red cells The assumption that the blue dye concentration ten minutes after the injection gives an accurate measure of the plasma volume has been criticised by Gregersen (1944), Davis (1942), and Rossiter (1949), since we were concerned with changes in the plasma volume rather than with the absolute amount, it seemed justifiable to use this convenient method

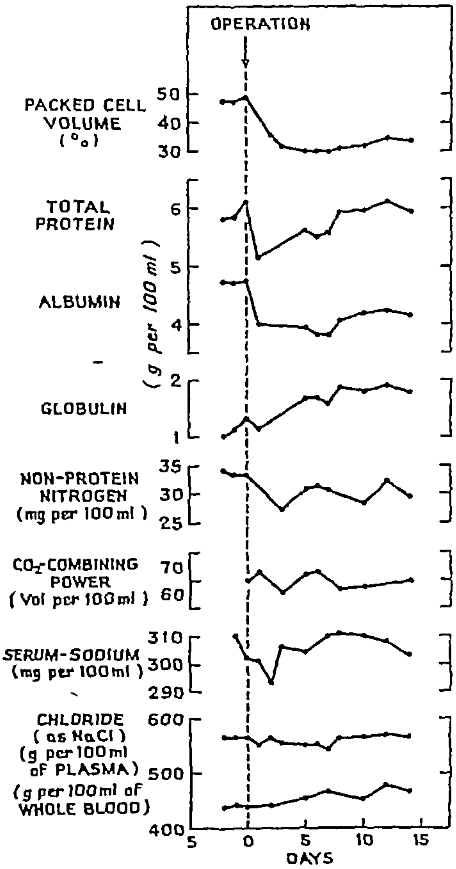

Fig 1—Typical changes in blood chemistry after partial gastrectomy.

RESULTS IN GROUP I

In the controls submitted to dietary restriction but not to operation significant changes were not observed in any of the blood constituents determined The following notes refer to the patients who underwent surgical operation The data from a typical case are given in fig 1

Plasma-proteins

About the second day after operation the total plasma protein fell sharply and remained low for two to twelve days The extent of the fall ranged in 16 patients from 0 29 to 2 0 g, with a mean of 0 73 g, per 100 ml of plasma It was the resultant of a rather greater fall in the plasma albumin *concentration* (which fell by 0 25–1 6 g, average 0 94 g, per 100 ml and remained below the preoperation level for the whole fourteen days' observation) and a gradual rise in the globulin level (which began immediately in all but 2 cases in which it followed an initial fall) It was this increase in the plasma globulin concentration which explained the early return of the total plasma protein level to, and often above, the preoperation level, while the plasma albumin concentration remained low

The different behaviour of the albumin and globulin fractions showed that the fall in total plasma protein concentration was not, as suggested by Coller et al. (1945) a mere dilution effect, from infusions of saline solution and glucose Nor was it due to deprivation of food, for it did not occur in the four unoperated controls, and in any case it appeared far more rapidly than the fall which does occur slowly in semi starvation (Keys et al 1946).

The picture somewhat resembles that seen in many cases of liver functional deficiency, but unfortunately no other tests of liver function were made

Non protein Nitrogen

In most of the patients the amount of non protein nitrogen was appreciably increased as early as the day after operation The magnitude of the increase and its duration varied Thus in one patient the biggest increase, on the fourth day after operation, was 6 4 mg per 100 ml, and on the seventh day the non protein nitrogen was still 3 mg per 100 ml above the pre operation level of 36 8 mg per 100 ml However, in a few patients there was no appreciable change in the non protein nitrogen. When there was, the increase in non protein nitrogen was due mainly to an increase in urea, but part was in the "rest fraction," there being no significant alteration in uric acid, creatinine, or amino acids There is an obvious relation in time between this rather variable increase in blood urea nitrogen and the increased protein katabolism after injury, usually reflected in the urinary excretion of nitrogen, and possibly the differences in magnitude of the blood urea increases may be associated with differences in renal function

Carbon Dioxide Combining Power

Although there were minor fluctuations in both directions, the carbon dioxide combining power of the plasma always remained within the accepted normal range of 55–75 volumes %

Red cell Volume

Measurement of the red cell volume by hæmatocrit showed that there was some hæmoconcentration immediately after operation and lasting from a few hours to forty eight hours Thereafter hæmodilution took place, its maximum—i e, the lowest hæmatocrit reading—being usually found between the fifth and the eighth day after operation The mean decrease in the hæmatocrit reading was 8 7% (range 3 0–16 0%), and there were corresponding decreases in the red cell count (mean decrease 840,000, range 280,000–1,120,000, per c mm) and amount of hæmoglobin (mean decrease 17 1%, range 8 0–24·0%, Haldane) These figures suggest that during the later period of hæmodilution there is either a decrease in the number of circulating cells or an increase in the plasma volume without either hydration or dehydration of the erythrocytes Data from a typical case are shown in fig 2 Preoperative levels were not regained during the period of observation shorter, until in September, 1949, he was vomiting every day and suffering from severe pain in the right hypochondrium passing through to the right shoulder blade At this time a barium meal showed pyloric stenosis, about 60% remaining in the stomach after twenty four hours Reluctant to take medical advice the patient continued living on an insufficient diet of bread and butter with fish and milk occasionally, until in an exhausted dehydrated condition he was admitted to the hospital under one of us (H H S) on Jan. 23 1950.

On admission he was poorly nourished and asthenic, weighing 6 st 9 lb height 5 ft 2 in He was collapsed, pale, and dehydrated, with a dry furred tongue, pulse rate of 60–70 per min, normal temperature, and blood pressure of 95/60 mm Hg He had a large stomach with visible peristalsis and succussion splash. His bowels had not opened for several days, and very little urine was being passed

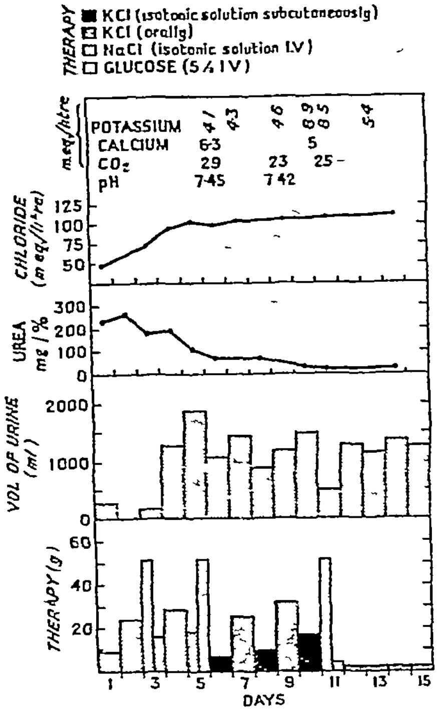

Fig. 1—Biochemical data.

Investigations showed salt-depletion and extrarenal uræmia Serum chloride 48 6 m.eq per litre (170 mg per 100 ml), blood urea 256 mg per 100 ml. Urine normal urinary chlorides 256 m eq per litre (Fantus test) Blood proteins albumin 3 9 g and globulin 2 8 g per 100 ml Fractional test-meal showed achlorhydria No occult blood in stools Red-cell count 4,150 000 per c.mm, Hb 11 6 g per 100 ml mean cell volume 80·9 c µ., mean corpuscular Hb concentration 32 7%

Treatment and Progress—On the second day the patient had two convulsions and rapidly became comatose Almost complete anuria was present and the blood urea reached 290 mg per 100 ml Treatment consisted of intravenous infusions of physiological saline and glucose solution (total sodium chloride 90 g and glucose 100 g) until, after five days the serum-chloride reached normal figures and the blood urea fell with the return of renal function (fig 1) The patient was now conscious but in spite of the apparent success of treatment from the biochemical aspect, he still remained drowsy, rousable but very irritable and incontinent He complained of great weakness, but there was no obvious dehydration His pulse-rate was slow (46 per min.), blood pressure 90/60 mm Hg and respirations so shallow as to be almost imperceptible, regular, but more rapid than normal There was a moderate degree of cyanosis Radiography of the chest was normal The peripheral reflexes were much diminished but plantar responses normal

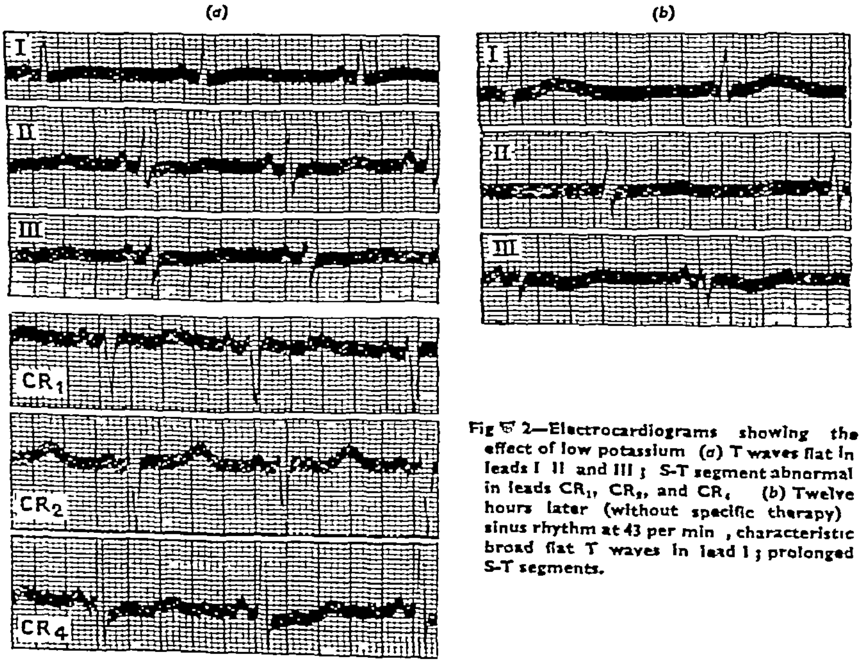

Fig 2—Electrocardiograms showing the effect of low potassium (*a*) T waves flat in leads I II and III; S-T segment abnormal in leads CR_1, CR_2, and CR_4 (*b*) Twelve hours later (without specific therapy) sinus rhythm at 43 per min, characteristic broad flat T waves in lead I; prolonged S-T segments.

It seemed that some other adverse factor must be present and the serum potassium level of 4 1 m eq per litre (16 mg per 100 ml) and the electrocardiogram (fig 2) were compatible with potassium deficiency By the sixth day the patient appeared to be in extremis An isotonic solution of potassium chloride (total 5 5 g) was injected subcutaneously in a drip over four hours with hyaluronidase Recovery began six hours after the start of this treatment, and by next morning the change was remarkable, the patient being alert, feeling very well, and boasting of his vitality His pulse and respirations were normal, blood pressure 120/80 mm Hg, and peripheral reflexes and electrocardiogram (fig 3) normal Potassium chloride was continued by mouth, 2 g being added to each two hourly feed

On the 8th day the patient began to deteriorate once more, becoming weak, rather drowsy and irritable, and he then suddenly collapsed into the same apparently moribund state as before, the electrocardiogram reverting to the hypokalæmic type Potassium chloride (total 5 5 g) in isotonic solution was again given subcutaneously at the same rate, and it produced a quicker recovery than before Some weakness, with diminished reflexes, slight drowsiness, and irritability persisted but gradually disappeared over the next twenty four hours and potassium chloride 3 g was given in each two hourly feed

In spite of receiving this potassium by mouth he had a further relapse on the tenth day, which was again relieved by subcutaneous potassium chloride (total 16 6 g over eight hours) This dosage, however, led to potassium intoxication, with characteristic changes in the electrocardiogram (fig 4) when the serum level reached 8 8 m.eq per litre (35 mg per 100 ml) The condition now was one of dehydration with malaise and brisk reflexes It responded readily to intravenous glucose (50 g) and sodium chloride (4 5 g), given to reduce the serum potassium level, and twenty four hours later the electrocardiogram was reversed and again suggestive of potassium deficiency

The man's subsequent progress was uneventful He was given potassium chloride 1 g twice daily and was fit for operation after a month Later investigations confirmed the absence of organic renal disease The urine was normal in all respects Van Slyke urea-clearance test was 91% Urea-concentration test (Maclean) gave a maximum figure of 3 6% urea, and Volhard's concentration and dilution tests were normal An intravenous pyelogram was also normal

Laparotomy confirmed the diagnosis of almost complete pyloric stenosis The pylorus and gall bladder were embedded in a mass of inflammatory tissue, probably from a previously leaking duodenal ulcer Partial gastrectomy being impossible, a gastrojejunostomy was done His recovery was uneventful, composition, though not pronounced, are against this view Thus, as early as the first day after operation there is a tendency for the plasma-albumin concentration to decrease and for the globulin concentration to increase, and the probable reality of these tendencies is emphasised by their more definite character on the second day Again, the plasma chloride and plasma sodium concentrations, though they have not much altered (see table), tend to decrease These findings suggest an alteration in capillary permeability such as has been proposed by Howland and Mahoney (1943) and support previous evidence—e g , Fox and Baer (1947)—for the accumulation of sodium and chloride in damaged tissue In so far as they suggest transference of albumin to the extracellular extravascular fluid, they indicate a reinforcement of conditions, initiated perhaps by the leakage of protein and inorganic ions from damaged tissue cells, which must lead to a widespread redistribution of body-water and electrolytes.

Considered in conjunction with previous observations on chloride, sodium, potassium, and water metabolism after surgical operations (Wilkinson et al. 1949, 1950), the small changes in the concentrations of the blood constituents indicate the efficiency of differential renal function in assisting the production of the inflammatory exudate They emphasise the true biological function of the blood as a vehicle The readiness with which albumin apparently passes out from the unusually permeable capillaries in the injured area suggests that this protein fraction has important functions apart from the maintenance of intravascular osmotic tension Whether the action of albumin is particularly to draw water from the capillaries to the seat of injury or to provide a local source of protein components for repair, or both, is unknown. It seems that apart from the reductions in the total quantity of albumin and in the volume of plasma in circulation, the bulk of the constituents of the inflammatory exudate is derived from the cells and the extravascular fluid in the uninjured areas. The initial disturbance at the time and site of injury may lead to the local production of some substance which affects not only the local capillaries but also, perhaps indirectly, renal function

SUMMARY

Changes in the composition and volume of the blood after severe surgical operations followed a general pattern which was independent of the type of operation or the method of postoperative feeding

In all the patients there was a sudden fall in the plasma protein, in particular the albumin concentration In most cases the globulin concentration gradually rose to values well above the preoperative levels

Increases in amount of non-protein (urea) nitrogen were observed in some patients

Hæmoconcentration on the day after operation, followed by hæmodilution, was observed in all patients. Changes in hæmatocrit values were accompanied by corresponding changes in red-cell count

An immediate reduction in total blood-chloride with an inconstant reduction in plasma chloride was followed in most patients by a rise in total blood-chloride There were corresponding changes in the serum-sodium There was some evidence that electrolyte ions were transferred from the plasma to the red cells

On the day after operation there was a significant reduction in plasma and blood volume, and in the total amounts of proteins and sodium circulating in the plasma, but no significant change in the "thiocyanate space"

The relation of the blood changes observed to the periods of salt retention and protein katabolism after operation is discussed.

We wish to thank Sir James Learmonth for providing clinical facilities and for his continued interest in our work. A grant was made to one of us (C P S) by the Medical Research Council for technical assistance and materials , and one of us (A W W) has held the Syme Surgical Fellowship at Edinburgh University during the course of these studies

THE importance of potassium as the chief ion of the cell and an essential factor in neuromuscular transmission has been known to physiologists since the end of last century but it is only in recent years that disturbances of potassium metabolism have been clinically recognised Thus in familial periodic paralysis a fall in serum potassium (hypokalæmia) has been shown to be the cause of the paralysis, which disappears when potassium salts are given (Aitken et al. 1937) Darrow (1946) made an exhaustive study of hypokalæmia in infantile diarrhœa and reduced their mortality from 25% to about 5% with replacement therapy The necessity for anticipating changes in potassium metabolism has also been demonstrated in renal conditions (Brown et al 1944) and in the recovery phase of diabetic acidosis, where the outcome may be fatal (Holler 1946) Hypokalæmia may also occur in Cushing's syndrome (Willson et al. 1940), in congenital alkalosis (Gamble et al. 1945), and after therapy with deoxycortone (Talbott and Schwab 1940, Ferrebee et al 1941), testosterone (Butler et al. 1942) or p aminosalicylic acid (Cayley 1950) The importance of potassium in surgical practice has been emphasised by Blixenkrone-Møller (1949)

Probably too little attention has been paid to the potassium ion when treating the profound electrolytic disturbances that accompany many gastro enterological conditions in the adult, particularly those associated with vomiting and diarrhœa. The present case is reported as a typical example of hypokalæmia and its dramatic response to specific therapy

CASE RECORD

A man, aged 47, gave a history of dyspepsia starting in 1930 the chief symptoms being epigastric pain one or two hours after food, eased by milk or alkalis and relieved by vomiting Bouts of vomiting and pain, interspersed with freedom from symptoms continued until 1946 when the pain became worse and changed to a griping which reached a climax about 3 P.M each day when the patient would vomit a large quantity of material in which undigested particles of his breakfast were visible The intervals of freedom became shorter, until in September, 1949, he was vomiting every day and suffering from severe pain in the right hypochondrium passing through to the right shoulder blade At this time a barium meal showed pyloric stenosis, about 60% remaining in the stomach after twenty-four hours Reluctant to take medical advice the patient continued living on an insufficient diet of bread and butter, with fish and milk occasionally, until in an exhausted dehydrated condition he was admitted to the hospital under one of us (H. H. S) on Jan 23 1950.

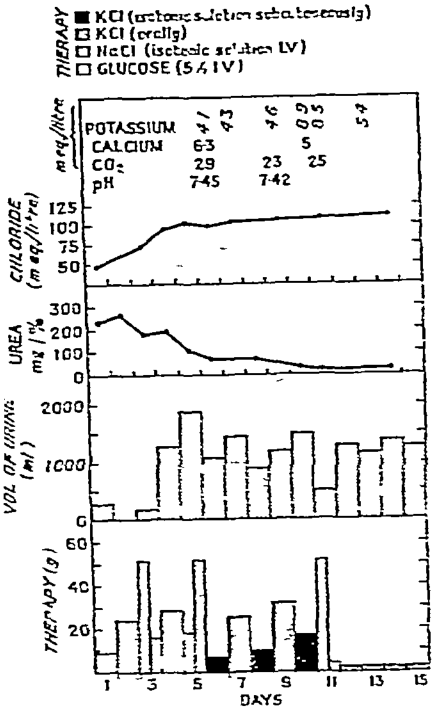

Fig. 1—Biochemical data.

On admission he was poorly nourished and asthenic, weighing 6 st 9 lb height 5 ft 2 in. He was collapsed, pale and dehydrated with a dry furred tongue, pulse-rate of 60–70 per min, normal temperature, and blood pressure of 95/60 mm Hg He had a large stomach with visible peristalsis and succussion splash His bowels had not opened for several days, and very little urine was being passed.

Investigations showed salt-depletion and extrarenal uræmia Serum-chloride 48·6 m.eq per litre (170 mg per 100 ml), blood urea 256 mg per 100 ml. Urine normal urinary chlorides 256 m.eq per litre (Fantus test) Blood proteins albumin 3·9 g and globulin 2·8 g per 100 ml. Fractional test-meal showed achlorhydria No occult blood in stools Red-cell count 4,150,000 per c.mm. Hb 11·6 g per 100 ml, mean cell volume 80·9 c.µ., mean corpuscular Hb concentration 32·7%

Treatment and Progress—On the second day the patient had two convulsions and rapidly became comatose Almost complete anuria was present, and the blood urea reached 290 mg per 100 ml Treatment consisted of intravenous infusions of physiological saline and glucose solution (total sodium chloride 90 g and glucose 100 g) until after five days, the serum-chloride reached normal figures and the blood urea fell with the return of renal function (fig 1) The patient was now conscious but in spite of the apparent success of treatment from the biochemical aspect, he still remained drowsy, rousable but very irritable and incontinent He complained of great weakness but there was no obvious dehydration. His pulse-rate was slow (46 per min.) blood-pressure 90/60 mm. Hg and respirations so shallow as to be almost imperceptible regular but more rapid than normal There was a moderate degree of cyanosis Radiography of the chest was normal. The peripheral reflexes were much diminished but plantar responses normal

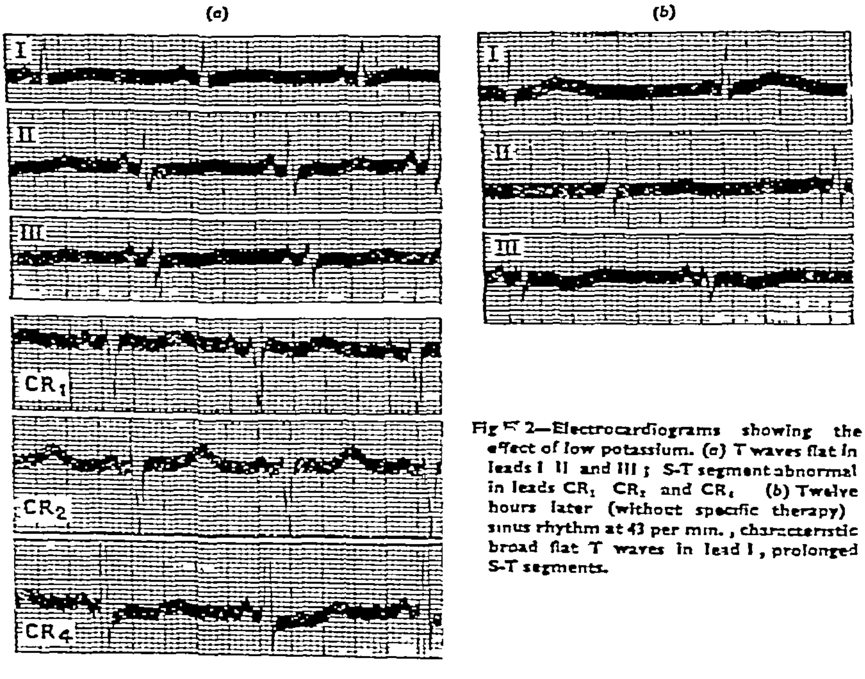
It seemed that some other adverse factor must be present and the serum potassium level of 4·1 m eq per litre (16 mg per 100 ml.) and the electrocardiogram (fig 2) were compatible with potassium deficiency By the sixth day the patient appeared to be in extremis An isotonic solution of potassium chloride (total 5·5 g) was injected subcutaneously in a drip over four hours with hyaluronidase Recovery began six hours after the start of this treatment and by next morning the change was remarkable, the patient being alert feeling very well, and boasting of his vitality His pulse and respirations were normal, blood pressure 120/80 mm Hg and peripheral reflexes and electrocardiogram (fig 3) normal Potassium chloride was continued by mouth, 2 g being added to each two hourly feed.

On the 8th day the patient began to deteriorate once more becoming weak, rather drowsy and irritable and he then suddenly collapsed into the same apparently moribund state as before, the electrocardiogram reverting to the hypokalæmic type Potassium chloride (total 5·5 g) in isotonic solution was again given subcutaneously at the same rate, and it produced a quicker recovery than before Some weakness with diminished reflexes slight drowsiness and irritability persisted but gradually disappeared over the next twenty four hours and potassium chloride 3 g was given in each two hourly feed

In spite of receiving this potassium by mouth he had a further relapse on the tenth day, which was again relieved by subcutaneous potassium chloride (total 16·6 g over eight hours) This dosage, however led to potassium intoxication, with characteristic changes in the electrocardiogram (fig 4) when the serum level reached 8·8 m.eq per litre (35 mg per 100 ml.) The condition now was one of dehydration with malaise and brisk reflexes It responded readily to intravenous glucose (50 g) and sodium chloride (4·5 g), given to reduce the serum potassium level and twenty four hours later the electrocardiogram was reversed and again suggestive of potassium deficiency

The man's subsequent progress was uneventful He was given potassium chloride 1 g twice daily and was fit for operation after a month. Later investigations confirmed the absence of organic renal disease The urine was normal in all respects. Van Slyke urea-clearance test was 91% Urea-concentration test (Maclean) gave a maximum figure of 3·6% urea, and Volhard's concentration and dilution tests were normal An intravenous pyelogram was also normal.

Laparotomy confirmed the diagnosis of almost complete pyloric stenosis. The pylorus and gall bladder were embedded in a mass of inflammatory tissue probably from a previously leaking duodenal ulcer Partial gastrectomy being impossible, a gastrojejunostomy was done His recovery was uneventful,



(a) (b)

Fig 2—Electrocardiograms showing the effect of low potassium. (a) T waves flat in leads I II and III; S-T segment abnormal in leads CR_1 CR_2 and CR_4 (b) Twelve hours later (without specific therapy) sinus rhythm at 43 per min., characteristic broad flat T waves in lead I, prolonged S-T segments.

with little disturbance in the serum electrolyte levels Six months later he felt perfectly well and had gained 33 lb in weight

DISCUSSION

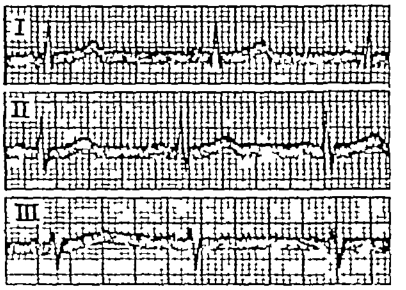


Fig 3—Twelve hours after fig 2(b), showing return to normal following parenteral potassium chloride

The biochemical pattern of this patient at first followed the course that is usual in pyloric stenosis with continuous vomiting Thus the loss of hydrochloric acid and water gave rise to hypochloræmia with alkalosis Finally, dehydration with an insufficient glomerular filtration pressure led to acute renal failure The delay in the man's recovery after correction of salt loss and return of renal function pointed to some complicating factor, and there were clinical indications of potassium deficiency These were the great muscular weakness with poor tone and almost absent reflexes the bradycardia, and respirations so shallow as to be almost imperceptible, resulting in cyanosis—a state of affairs reminiscent of Holler's (1946) case where a Drinker respirator was necessary until the administration of potassium produced a prompt recovery of respiratory function The earliest warning of the relapse when parenteral potassium therapy was discontinued was a change of personality, consisting of irritability and apathy, together with asthenia and diminution of reflexes The reversal of these attacks by a single line of therapy on three separate occasions confirmed the diagnosis

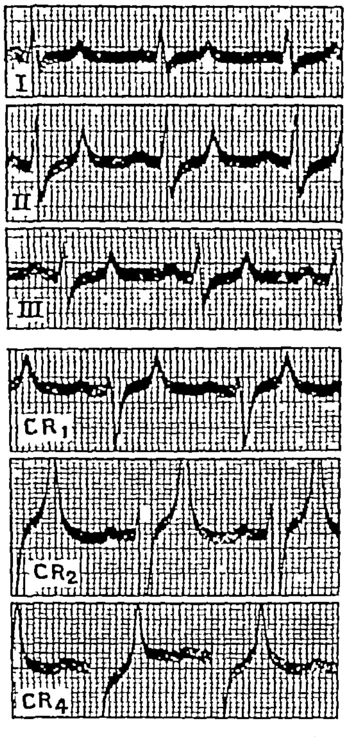

Fig 4—Electrocardiogram indicating potassium intoxication; T waves now tall and spiky

Biochemical evidence was supplied by the serum potassium levels, estimated by the usual chemical methods The flame photometer, which makes estimation easy and rapid, was not then available The normal amount of potassium in the serum is minute, being 4–6 m eq per litre (16–22 mg per 100 ml), and in both these techniques the slightest hæmolysis in the blood sample will lead to false high figures owing to contamination of the serum by the high concentration of potassium from the erythrocytes The figures in the present case were only on the low side of normal and not so low as would be expected with potassium deficiency causing serious symptoms But the essential deficiency is intracellular, and there is no way, apart from muscle analysis, of measuring the cellular potassium Symptoms of potassium deficiency may arise although the serum potassium level is normal, and, in cases where dehydration results in the removal of intracellular fluid and the transfer of potassium to the serum, the serum potassium levels may temporarily be higher than normal before excretion in the urine has taken place Such cases can only be detected by potassium balance experiments. Generally, the serum potassium, which accurately reflects the potassium level in the extracellular fluid bathing the cells (Folk et al 1948), is an accurate guide to the presence of this syndrome

Electrocardiography proved to be the quickest method of detecting changes in potassium metabolism in the present case Both rises and falls in the serum potassium level affect the cardiac mechanism, as Ringer showed when developing his solution to perfuse the isolated mammalian heart (Ringer 1883), and other workers who have studied the electrocardiographic responses to variations of serum potassium in man have shown that a low serum potassium level is associated with a flat broad T wave and a prolonged Q–T interval. Later there is further lowering of the T wave, then depression of the ST segment, eventually leading to heart block and heart failure in systole (Stewart et al 1940, Stoll and Nisnowitz 1941) Raised levels of serum potassium produce high T waves, followed by auricular arrest, prolonged Q R S complex, and heart failure in diastole from a direct depressant action of the potassium ion on the myocardium (Winkler et al 1938, Tarail 1948) The prolonged flat T wave (fig 2*b*) in the present case and an associated long QT interval were typical of potassium deficiency, and returned to normal after therapy This had been shown by Thomson (1939) who demonstrated a direct correlation between the serum potassium level and the height of the T waves The alteration following specific therapy is important because other factors in the electrolytic pattern may play a part in the electrocardiographic changes, notably hypocalcæmia (Barker et al 1937), which was unlikely in the present case because the serum calcium level was normal. Overdosage with potassium later produced intoxication, with remarkably high peaked T waves, similar to those reported in a fatal case by Finch and Marchand (1943) The serum potassium level had then risen to 8 8 m eq per litre (35 mg per 100 ml), and the patient had severe malaise and water depletion All these features disappeared after the administration of intravenous glucose which lowers the serum potassium level (Fenn 1939), and physiological saline

The sequence of events leading to symptoms of hypokalæmia probably occurred on a background of deprivation, for the intake had long been inadequate The expenditure of cellular elements by the body for energy, heat, and repair, which occurs during starvation, probably contributed to the deficit, while further accentuation would follow the continuous vomiting and gastric aspiration, for the fasting gastric juice contains about 80–90 mg of potassium per 100 ml Dehydration also contributed by loss of potassium with the intracellular fluid

The effect of treating such a patient with large quantities of intravenous sodium chloride is not only to increase any potassium deficit (Stewart and Rourke 1942) by causing a potassium diuresis (Gamble 1942), possibly aggravated by defective tubular function (Burnett et al. 1950), but also to substitute sodium for potassium in the cells, an exchange that has been shown by muscle analysis (Mudge and Vislocky 1949) to be a feature of alkalosis There seems, in fact, to be a reciprocal relationship between sodium and potassium, and the giving of generous infusions of sodium chloride as a routine may be ill advised and even dangerous unless their amount is controlled by frequent serum potassium estimations It is indeed surprising that hypokalæmia does not occur more often in undernourished patients with vomiting or diarrhœa who are treated with massive infusions Perhaps it goes unrecognised. That low serum-potassium levels are not uncommon in pyloric stenosis was shown by Falconer et al (1939), and Bellett (1950) mentions that among a series of 25 cases with vomiting due to intestinal obstruction there were several with symptoms similar to those in our patient which responded to potassium therapy

The details of potassium therapy have been reviewed by Howard and Carey (1949) Treatment is hazardous unless care is used, and accurate dosage is impossible unless a quick method of estimation is available An excess of potassium may cause cardiac arrest This is more likely to happen with intravenous infusions, and Howard mentions a case where the cardiac changes were being recorded on a continuous electrocardiogram when, without warning, the patient collapsed with heart failure in diastole It is not the total dose that is so important, provided renal function is adequate, but the amount of serum-potassium reaching the heart This can be controlled by the rate of injection, and the lethal threshold is about 10–12 m eq per litre In the present case the subcutaneous method was chosen because we have found subcutaneous infusion with hyaluronidase very satisfactory, and believe that it is safer than intravenous infusion The administration of potassium chloride by mouth was ineffective, probably owing to defective absorption due to the almost complete pyloric stenosis Large doses of potassium chloride (total 29 7 g) had to be given parenterally as a life saving measure before the tendency to relapse was overcome This was to be expected, and it may take fourteen days, or longer, before the potassium of the body is replenished

SUMMARY

A patient with advanced pyloric stenosis suffering from salt depletion and extrarenal uræmia was only temporarily benefited by glucose saline infusions His apathy, muscular atonia, bradycardia, and shallow respirations pointed to potassium deficiency, which was confirmed by the electrocardiographic findings and was not excluded by a serum-potassium level only on the low side of normal

Ætiological factors, such as undernutrition, vomiting and dehydration are discussed, and the dangers of infusing such a patient with sodium chloride are indicated.

Early recognition of hypokalæmia is of great importance in such cases which do not respond to the usual treatment of salt depletion and uræmia

In the present case, the subcutaneous infusion of potassium chloride resulted in dramatic improvement in the symptoms and reversal of the electrocardiographic abnormalities For a time the symptoms of hypokalæmia returned if the infusion was stopped, but ultimately the patient fully recovered

We wish to thank the electrocardiographic department, under Prof K. D Wilkinson, for invaluable coöperation in this case, and Dr Garfield Thomas for the biochemical estimations also Mr D F Cole B SC for his advice on the paper

WEST MIDDLESEX HOSPITAL, ISLEWORTH

POTASSIUM deficiency in steatorrhœa has been described in 2 cases by Harrison et al (1943) and in 1 case by Engel et al (1949) All the patients had a low serum-potassium level associated with muscular weakness An increased fæcal excretion of calcium and phosphorus is well known to occur in steatorrhœa, but abnormal loss of potassium and sodium in the stools has rarely been reported (Black 1946, Harrison et al. 1947)

The case described here is one of idiopathic steatorrhœa showing low serum potassium levels and a markedly increased fæcal excretion of both potassium and sodium

Technical Methods—Sodium and potassium were determined on ashed fæces and urine after removal of interfering substances by methods essentially similar to those described by Hawk et al (1947) The sodium and potassium concentrations in the resulting clear filtrates were estimated by the same methods as for serum. Serum potassium was determined by the method of Jacobs and Hoffman (1931), and serum sodium by that of McCance and Shipp (1931)

CASE RECORD

A woman, aged 41 was admitted on May 3, 1949, with two weeks history of diarrhœa Owing to her low level of intelligence no clear previous history could be obtained

On admission she looked ill and wasted There was general weakness but this was in keeping with her illness The tongue was smooth and sore and there were fissures at the angles of the mouth Blood pressure 105/80 mm Hg No abnormalities were found in other systems There was no evidence of tetany From 5 to 10 fluid stools were passed daily
